LUCIFER DYES FOR BIOLOGICAL TRACING

Michelle Chilen

The samples you can analyze with half a bottle of Ampholine

Cut your electrofocusing costs to a fraction of previous levels without sacrificing quality or resolution. Save substantial time casting, running, and staining gels as well. High performance electrofocusing lets you analyze well over 600 samples per bottle of Ampholine. And if you're struggling with an especially tight budget this year, we can help you save even more. High performance gels are cast by capillary action onto thin plastic support foils in layers a mere 0.5 to 0.25 mm thick. Because the new thin gels are cooled more efficiently, resolution-robbing thermal gradients are eliminated while run times drop to as little as 30 minutes.

Ampholine, the LKB tradename for the world's largest selling carrier ampholyte, is now available in four new pH ranges. The new ranges are specially preblended for direct use in either acrylamide or our new agarose gels and exhibit excellent conductivity and reproducibility. By switching

to our new preblends, you'll save preparation time and reduce your stocking costs as well.

High performance electrofocusing is just one of a series of new and improved techniques you can perform on the Multiphor® System. For more details about this and other new kits soon to be released, contact your local LKB representative. We have offices everywhere. Or phone us today at one of the addresses listed below.

Microflex FX Series Photomicrography with Electronic Precision

It was worth it.

At first we weren't making our own enzymes. We were buying them. Then we learned something you probably know already – enzymes pure and reliable enough for DNA-RNA studies are not easy to come by.

So we made our own, to our own standards. And before long other researchers wanted to buy *ours*, for the same good reasons.

So we named them NENZYMES and produce them in quantity, but we still subject them to the same very rigorous tests as before. And we provide complete testing

data - so you'll know exactly what you're getting.

It's a lot of work to make and test the purest enzymes, but it's worth it. There are enough variables in molecular biology research as it is.

DNA Polymerase I, Large Fragment DNA Polymerase I (Klenow Fragment), T₄-Polynucleotide Kinase, T₄-DNA Ligase, and RNA Polymerase. Plasmid pBR-322 and ϕ X174 (RF I) DNA also available. Call collect for complete information.

One Apparatus-Two Formats

Versatile Verticals

... Introducing the BRL® Tube Gel Module for the Model V16

The Model V16 Vertical Gel Electrophoresis System, our low-cost, performance proven apparatus, now provides an extra measure of versatility with the unique Tube Gel Module accessory. This feature allows you to run both tube gels and slab gels in the same compact system.

Features:

Instantly converts the Model V16 from Slab Gels to **Tube Gels**

With the Tube Gel Module in place, up to 12 gel tubes 140mm long in either 3mm or 6mm diameter can be run in the Model V16. Useful for a variety of classical 'disc' gel and isoelectric focusing (IEF) applications, this combination is ideal for the O'Farrell high resolution 2-D separation method.

Complete, low cost system

The Tube Gel Module consists of an upper buffer chamber with platinum electrode, safety lid and power cords. Each Module is supplied with twelve 3mm I.D. tubes, twelve 6mm I.D. tubes, grommets for both, and stoppers to seal unused positions.

Bevelled Glass Plate

BRL also offers this sturdy, bevelled glass plate to replace the standard rear plate when running the second dimension of the 2-D protein gel procedure.

Printing Counter/Timer

16 individual parallel inputs microprocessor based

- * Prints results in programmable intervals (1 to 99 min.) or on demand.
- * Prints clock time: hours, min., sec.
- * Counts pulses or contact closures from 16 sources
- * 99999 counts capacity in each channel.
- * Totalizes time from 16 individual inputs with 4 msec. resolution.
- * Prints individual labels for each source.
- * Stores information on magnetic tape.
- * Functions as general purpose microcomputer.

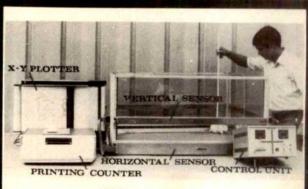

We are looking for representatives.

5nm guaranteed resolution and corrected field objective and...

...JEOL long term instrument reliability — backed by dedicated technology and decades of experience. Have a demonstration, see the sheer quality of the image display and experience the effortless performance, precision specimen handling and ease of operation.

- New corrected field objective and gun geometry guarantees 5nm (50Å) resolution. Most laboratory sites will attain 4nm (40Å) with standard tungsten hairpin
- Working distances 12 to 39 mm and beyond with continuous focus control and automatic magnification correction throughout
- * New X-Y stigmator with calibrated controls, electric alignment and direction indicators
- Focus wobbler switching for accurate aperture alignment for high resolution use and optional wavelength and energy dispersive analysis attachments
- New ABC-automatic brightness control ensures constant display brightness when moving specimens and changing operating parameters
- New LED displays of image contrast and brightness for rapid check of photographic conditions
- * 10X to 180 000X magnification range
- * 0-39kV accelerating voltage
- 360° rotation, 60° eucentric tilt stage

How Britain runs its Science

How the US runs its Science

These two new Nature wallcharts are now available.

The 2 x 3ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments.

Designed as fold-out sheets, the wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from Nature's offices in London. Basingstoke and New York.

Becton Dickinson FACS Systems

ADVANCES IN CELL BIOLOGY

The Fluorescence Activated Cell Sorter (FACS) has become a powerful means of identifying and separating cells and cell constituents according to distinctive properties of FLUORESCENCE and SIZE. FACS makes possible multiparameter measurement of individual cells, providing the distribution of these measurements in a sample. Evaluation against operator-selected criteria, at rates to 5,000 cells per second, forms the basis for physical separation of viable subpopulations. FACS measurements have been documented for sensitivity to as few as 3,000 fluorescent molecules per cell Light-scatter measurements are sensitive to particles as small as 0.3 micron in diameter, and can be used to detect viability, without staining, in homogenous populations such as lymphocytes. FACS Systems are ac-cepted as the standard of comparison for quality, performance and reliability, and are in daily use in top laboratories worldwide. Following is a brief view of recent FACS advances:

Cell Cycle after Simian Virus-40 Infection

FACS has been used to study the interplay between Simian Virus-40 (SV-40) and host cells after infection of growing cell cultures. Both mockand SV-40 infected cultures have been harvested at 24 to 48 hours after infection, stained for DNA content, and analyzed with FACS for cell cycle distribution. Infected cultures exhibited a marked shift to above average G2 DNA content by 24 hours after infection, and remained in this state for at least 24 hours further, indicating that after infection, cycling cells completed one round of DNA synthesis, but remained undivided.

Live/Dead Cell Enumeration

The forwardangle lightscattering measure-ment of FACS can be used to discriminate viable and nonviable cells in homogeneous populations, such as lymphocytes. FACS analysis during a lymphocytotoxicity

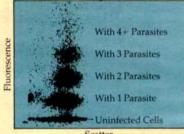

test of mouse spleen cells reacted with varying dilutions of rabbit anti-mouse T-cell antiserum plus complement has shown that as antiserum concentration increases, the percentage of cells in the dead subpopulation also increases.

Sorting of Erythrocytes Containing Malaria Parasites

Plasmodium berghei-infected mouse erythrocytes can be analyzed and sorted on the basis of parasite DNA content. Infected cells, treated with a vital DNA-binding dye, fluoresce with intensity corresponding to the number of parasites contained. Uninfected cells are nonfluorescent. Measurements of light scatter and fluorescense intensity from each cell are displayed as a correlated dot plot,

as shown. Sorting of uninfected from infected cells enables subsequent studies.

For additional information, including an extensive bibliography, call or write Becton Dickinson FACS Systems.

Reader Enquiry Card 15 on

No other commercially available cell sorter and analyzer approaches the power, precision and versatility of the Ortho Systems 30/50. The instrument is offered in two basic configurations: System 30—a high resolution, 21 parameter analytical flow cytometer, and System 50—which adds cell sorting capabilities to the System 30 flow cytometer. Both feature dual lasers as standard equipment for increased analytical power.

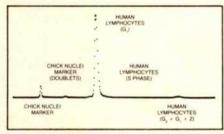

System Components

To appreciate the far-reaching capabilities of these Ortho instruments, consider that the System 50 combines: two lasers-a .8 milliwatt helium-neon for ultra high precision scatter measurements and a 5 watt argon type for fluorescence measurements (optional argon-ion, and krypton-ion lasers with U.V. capability are available); four detectors-two of the photo-multiplier type for right angle scatter, and fluorescent emission detection (S-20 response, 185 nm-850 nm), and two solid state sensors for axial light loss and narrow angle forward scatter: a sophisticated optical system incorporating fiber optics: a multiplexed multichannel analyzer, with C.R.T. display: the signal processor unit: and an advanced cell sorter module. Additionally, the Model 2150 computerized 8 parameter data handler/sorter controller is available as an option* The 2150 System features

 Histogram of CHO chromosomes stained for D.N.A. Ethidium Bromide/Chromomycin A₃.

Cytofluorograph System 50H Laser-250mw @ 457nm. Red Fluorescence

2. Histogram of human lymphocytes utilizing a chick nuclei marker for standardization and stained for D.N.A. with Propidium Iodide. C.V. = 1.65% (Human Lymphocytes)

simultaneous data acquisition, and real time processing while sorting is in progress.

System Capabilities

Together, these modules allow the System 50 to provide and analyze morphological information—a significant first for a flow cytometric instrument. With four detectors and the ability to display pulse height, pulse area or pulse width analysis for each—a total of 21 distinct measurement parameters can be studied.

The System 50 also features: two bidimensional regions of interest, dual histogram multi-channel analyzer with cytogram mode, super-sil quartz optics with which the cells are analyzed and easy sample entry.

In order to provide customers with complete support, Ortho maintains an Applications Laboratory that is available for confirmation and consultation services. Additionally, an international network of service technicians is ready to aid customers should calibration or repairs ever be required.

Remarkable Results

The histograms and cytograms displayed were produced by the System 50. Evaluate them. And consider the difficulty of deriving this data by any other means. The capabilities of this unique Ortho instrument will speak for themselves.

State-of-the-art cell sorting and analysis from Ortho

BRL PRODUCT REVIEW

Bethesda Research Laboratories, Inc. P.O. Box 577 Gaithersburg, Md 20760

BRL GmbH Offenbacher Strasse 113 6078 Neu Isenburg West Germany

New Literature: BRL 81/82 Catalog

The 197 page master catalog contains over 300 products from five product lines: molecular biology, protein biochemistry, cell biology, immunology and research apparatus. Of special interest is the expansion of product offerings in the biological chemistry area. Circle No. 55 on the Reader Inquiry Card.

Remazol™ Blue Agarose

Remazol Blue Agarose is an experimental dye-ligand chromatography matrix with the striking property of not binding to human serum albumin. The chromatography matrix is a potentially useful alternative to Cibacron Blue Agarose (which does bind serum albumin) for protein purification.

Circle No. 56 on the Reader Inquiry Card.

*American Hoechst Corporation *Ciba AG

RPC-5 Analog

RPC-5 Analog is a matrix for nucleic acid chromatography with performance properties similar to the well-characterized RPC-5. RPC-5 Analog is a useful analytical and preparative tool for fractionation of DNA fragments produced by restriction enzyme cleavage, complementary strands of individual DNA restriction fragments, oligomers of single-stranded DNA and RNA, and active mRNA's. RPC-5 chromatography has been useful in isolating bacterial plasmids from cellular lysates and in recovering inserts cleaved from cloned plasmids by restriction enzymes. BRL has developed a method for batch preparation of plasmid DNA using RPC-5 Analog.

Circle No. 57 on the Reader Inquiry Card.

Hybri ● Dot

BRL has designed a 96 well manifold that simplifies scale-up of the sensitive "dot hybridization" procedure for detection of specific DNA and RNA sequences. In this procedure, as little as one picogram of a specific nucleic acid sequence, bound to nitrocellulose as a small spot, can be detected using ³²P-labeled probe (~108 dpm/µg). Dot hybridization has been used to detect viral DNA in lymphocytes and in serum.

Circle No. 43 on the Reader Inquiry Card.

Fibronectins: Antigen and Antibody Products

Fibronectins are high molecular weight adhesive glycoproteins found in plasma and on cell surfaces. Although biochemically and immunologically similar, cellular and plasma fibronectins are not functionally identical. Fibronectins from both sources possess the ability to enhance the attachment of cells in culture to the usual substrates and to induce the spreading of cells. However, cellular fibronectin is 50 to 100 times more effective both in aggregating red cells and in restoring normal morphology to transformed cells in culture.

Each product is supplied with a BRL Product Profile with specific product information and details of quality control assays.

Mouse Monoclonal Anti-Human Fibronectin (MCA-HFn)

Mouse Monoclonal Anti-Human Fibronectin is an IgG antibody that reacts with the plasma and cellular forms of fibronectin as determined by enzyme-linked immunoabsorbant assay (ELISA). Each lot is assayed for Protein A binding, cytotoxicity, and antibody titer. Available now, MCA-HFn is the first in a series of monoclonal antibodies to extraceffular matrix components.

Monospecific Antibodies to Human Plasma Fibronectin

The IgG fraction from antisera produced in rabbit and goat is purified by ammonium sulfate fractionation and ion exchange chromatography. These fractions are homogeneous as determined by SDS-PAGE (heavy and light chains) and the specificity is assayed by immunoelectrophoresis.

Monospecific Antisera to Human Plasma Fibronectin

Monospecific antisera to human plasma fibronectin is produced in rabbits and goats. The specificity of the antisera is established by immunoelectrophoresis. The specific antibody content is determined for each lot by quantitative precipitin analysis.

Human Cellular Fibronectin (HC-Fn)

Human Cellular Fibronectin is affinity purified from human foreskin fibroblasts and is supplied frozen in 100 mM CAPS buffer, pH 11.0 at a concentration of 1 mg/ml.

Human Plasma Fibronectin (HP-Fn)

Human Plasma Fibronectin, purified to homogeneity by gelatin-agarose affinity chromatography, is supplied as a lyophilized solid. Purity is established by SDS-PAGE and each lot is assayed for cell spreading activity.

Chick Cellular Fibronectin (CC-Fn)

Chick Cellular Fibronectin is isolated from chick embryo fibroblasts and purified to homogeneity by urea extraction procedures. CC-Fn is supplied frozen in 100 mM CAPS buffer, pH 11.0 at a concentration of 1 mg/ml.

Bovine Plasma Fibronectin (BP-Fn)

Bovine Plasma Fibronectin is a partially purified product especially suited as a supplement for routine tissue culture. Available as a lyophilized powder, each lot is assayed for cell spreading activity.

Circle No. 59 on the Reader Inquiry Card.

RNA Polymerase II

BRL is pleased to make available for the first time RNA polymerase II from calf thymus. As an alternative to the BRL eukaryotic in vitro transcription system, researchers can now construct a transcription system based on the BRL® RNA polymerase II (calf thymus) and a S-100 fraction from KB cells.

Circle No. 58 on the Reader Inquiry Card.

Restriction Endonuclease Xma III 5'C GGCCG3'

Xma III is isolated from Xanthomonas malvacearum by a modification of a published procedure. Xma III is the first restriction endonuclease known to recognize the sequence 5'C♥GCCG3' which contains two CpG nearest neighbor pairs. Since this nearest neighbor pair is relatively rare in eucaryotic DNA, the mean fragment size following complete digestion with Xma III would be expected to be large. In the case of Xma III cleavage of Drosophila DNA this is in fact observed. Cloning vehicle pBR322 has a single Xma III site at position 938.

Circle No. 44 on the Reader Inquiry Card.

T4 RNA Ligase

T4 RNA ligase is purified by Bethesda Research Laboratories from T4 infected E. coli B cells. This enzyme joins the 3' hydroxyl end and 5' phosphoryl group of RNA chains in both intra and intermolecular arrangements. It also catalyzes the addition of ribonucleoside 3', 5'-diphosphates or 2' deoxyribonucleoside 3', 5'-diphosphates to 3' termini of oligonucleotides. This reaction is especially useful for labeling RNA in vitro for sequence determination. Recently this enzyme has also been found to be capable of joining single strand oligodeoxyribonucleotides. The BRL® T4RNA Ligase is purified free of RNAse, 3' and 5' exoribonuclease, DNAse, 3' and 5' exodeoxyribonuclease, phosphatase and DNA ligase. Circle No. 45 on the Reader Inquiry Card.

Nuclease P1

Nuclease P1, purified from cultures of *Penicillium citrinum*, is now available from Bethesda Research Laboratories. This enzyme is highly useful in the analysis of the 5'-terminal nucleotide of RNA and DNA in nucleotide sequence studies as well as in determinations of cap structure of eukaryotic mRNAs.

Data recording and analysis:

meet the time shrinker!

If you need to record and analyse data from multiple inputs, consider the advantages of using the Microdata M1600L data logger.

Magnetic tape cartridge Because it records on a standard 1/4 inch magnetic tape cartridge in ECMA/ANSI format, the output can be replayed at high speed into a computer, calculator or other data processing equipment. Alternatively, the internal replay facility of the data logger can be used. No other data logger has this capability.

Individual conditioning cards Individual, plug-in signal conditioning cards are used-one for each of the 20 input channels (expandable up to 100). As a result, each customer receives a bespoke instrument ready to handle mixed

analogue and digital inputs from most transducers. Cards are available at low cost to condition virtually every type of electrical signal, to reconfigure the instrument for different projects. No other STATION ROAD, RADLETT, HERTS, WD7 8JN. data logger offers these facilities.

Exceptional versatility The M1600L is available either as a mains powered, free-standing, laboratory instrument or in the portable weatherproof form operating from its internal batteries. For more permanent installation in existing systems, it can be supplied in chassis form for mounting in a 19 inch rack. No other data logger displays this versatility.

The M1600L is now widely adopted for projects in energy, transportation, agricultural and environmental research. If you would like further details, please

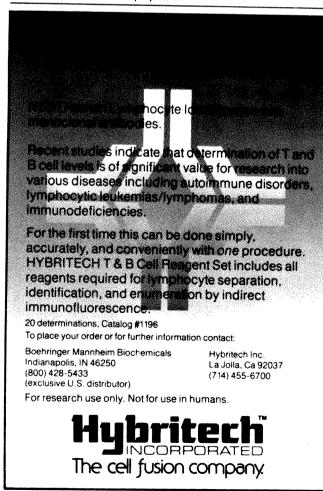

write, telephone, or return this advertisement clipped to your letterheading.

EULTO

Computer controlled BIJISA

FAST - Reads each 96 well plate in less than 40 seconds. Results printed out on thermal printer.

- ACCURATE Unique blanking feature automatically subtracts pre-incubation values from post-incubation values on up to ten plates in one run at the same wavelength. The end point is determined with extreme accuracy by:
 - Eliminating optical imperfections.
 - Eliminating contaminants absorbing in end point wavelength or other wavelengths.
- EASY TO USE Operator instructions displayed on VDU. Single key initiation of reading sequence.
 - RELIABLE Pre-incubation, post incubation and evaluated values and categories are printed on thermal paper.
 - Readings can be stored on disc for future recall and evaluation.
 - Unique feed back system eliminates drift problems through automatic calibration.
 - System automatically alerts operator and awaits corrections for: Readout values outside control sera values.

Wrong filter wavelength. No filter, incorrect optical alignment. Burned out light source.

- POWERFUL 48K Mini-computer with floppy disc, 9600 readings on data disc. Optional five disc drive version allows up to 48000 readings to be stored.
 - Software package supplies with system:
 - Evaluates control sera to indicate improper results.
 - Evaluates experimental values into High Positive, Mid-Positive, Low-Positive, Equivocal and Negative categories.
 - Allows user to define test name, lot number and constants.
 - Stores defined parameters on discs which can be changed as and when desired.
 - Additional software can be supplied by Artek or your own software department.

VERSATILE - Can be used as an independent laboratory minicomputer with built-in disc drive and printer. Both hardware and software designed to adapt to future trends in measurement technique. Unlike other readers, this system will never become obsolete.

> Custom programme service available for individual requirements.

Local sales and service support available throughout Europe. Write, phone or circle the reader reply card for details!

Definitive, Complete, Authoritative

NATURE announces the publication in 1981 of the Annual Directory of Biologicals and Disposable Chemicals. The directory will be available for distribution to all NATURE subscribers in the Autumn of 1981. It will also be marketed separately, offering an even larger distribution.

A New Buyers guide

The basic thrust of the directory will be to provide NATURE subscribers with a definitive reference catalogue from which they may purchase the chemicals and disposables listed.

From research conducted around the world the NATURE marketing staff has determined the need for a directory of biologicals, disposable chemicals and gases. Probably more than any other scientist, the NATURE reader represents the largest potential market for the sale of these chemicals.

Every attempt will be

made to produce a catalogue that will reference the worldwide market of chemical manufacturers, distributors, suppliers, and exporters.

No instrumentation or apparatus listings will be included in this directory; its sole purpose is to provide detailed information for our readers as to where they may secure the biologicals, chemicals and gases for use in their

laboratories.
The directory will be cross-referenced and include chemical classifications, product classifications, geographical location of suppliers and other referenced information as needed.

NATURE Directory of Biologicals

What's in It?

The directory will include (but not be limited to) these biological reseach chemicals

- immunochemicals
 - cell lines
 - fine chemicals
 - reagents
 - enzymes
 - isotopes
 - monoclonals
 - gases, etc.

Companies write for details NOW!

I'm interested in knowing more about Nature's new Directory of Biologicals.

Fighting tsetse flies and people

Opinions differ on the benefits of the transformation of the Punjab in India by the green revolution. Some hold that the transformation of traditional social life has been disastrous. Others, including most of those who live there, hold otherwise. If new strains of wheat have made it possible for India, for the first time in living memory, to be self-sufficient in wheat and thus realistically capable of turning its attention to other than agricultural development, who except those who fear competition in manufactured goods from India can count that a simple tragedy? Is it not, instead, natural to hope that similar transformations will be accomplished in other developing countries? This is the spirit in which, since the early 1970s, the World Bank has been organizing a confederation of donor governments and foundations, known as the Consultative Group for International Agricultural Research, whose frank objective has been to use the model by which the various strains of Mexipak wheat were developed by Dr Norman Borlaug (with imaginative support from the Rockefeller Foundation) to work similar revolutions elsewhere. Inevitably, not all the thirteen research institutes now under the group's wing have been equally successful. The most conspicuous cloud on the horizon is the problem of the International Laboratory for Research on Animal Diseases in Nairobi, now about to appoint its fourth director in seven vears.

The Nairobi laboratory (known as ILRAD) has been from the start the odd man out, but for good reason. Its origins lie in the accurate calculation that one of the most serious problems with which African agriculture must contend is that of the tsetse fly. The fact that the trypanosomes for which the tsetse is a vector cause African sleeping sickness among human beings is economically and socially important, but the loss of agricultural productivity because large tracts of Africa cannot be used for growing cattle is a more immediate obstacle to change. So what could be more natural than to set up (in 1974) a research institute for the battle against the tsetse fly? That was the calculation. Broadly speaking, the calculation was correct; a handful of dedicated and able scientists in Nairobi have been able to make substantial progress. There is talk of vaccination (of cattle) and of the development of resistant breeds. The trouble is that the laboratory and its management have been fighting not merely against the tsetse fly but also among themselves.

The most spectacular casualty of this squabbling is Dr A. C. Allison, whose resignation after a dispute with the board of trustees was required just a year ago. Can a laboratory that so lightly dispenses with the services of such a distinguished immunologist have serious work to do? That is what outsiders are bound to think. In practice, the board of trustees has scraped along, appointing an acting director of the laboratory first (for three months from 1 January this year) Dr C. Wells, the new chairman of its trustees, previously the head of the Canadian public veterinary service who is, by common consent, the man most likely to rescue ILRAD, and then Professor R. Zwarte from the University of Utrecht, who is also the chairman of the search committee for the new director of the laboratory. Between them, the members of the search committee have recommended to the trustees that the fourth director at ILRAD should be Dr Ross Gray from the University of Edinburgh. At their next meeting towards the end of July, the trustees will be required to decide one way or another.

Trustees of all kinds of bodies are constantly being faced with such dilemmas; which of two proposals to plump for? On this occasion, the managers of ILRAD should firmly say that they are not ready to make such a simple choice. In due course, to be sure, they may be able to enjoy such a clear-cut luxury. Before that, however, they must understand what has gone wrong at Nairobi. Why have they quarrelled so much among themselves (and why have they nevertheless allowed their numbers to grow)? How does it come about that so much good research has been done at ILRAD while such bitter fights have been carried on? Could it perhaps be that those working at the bench know as clearly as they that Africa will not feed itself until the tsetse fly is beaten? And if so, should they not invest time in putting their structure right? The cause is too good to be neglected.

Loose ends on evolution

Next week the trustees of the British Museum (Natural History) will be meeting and will probably be mulling over, as has been their custom for the past several months, the latest batch of correspondence to appear in Nature and elsewhere about the museum of which they are the custodians (and whose name they should change). Some weeks ago (see Nature 4 June, p.373), Sir Andrew Huxley was complaining at the centenary celebrations of the "obscurities and irrelevances" of much of this correspondence, but it is improbable that the trustees will feel able to skip that part of their agenda. By way of explanation, Sir Andrew also invited his listeners to reflect that in giving houseroom to these supposedly empty but entertaining letters, Nature was simply following other commercially-based journals which supply their readers with sensation. (The treatment by The Times of London of a recent sensational murder trial was mentioned.) Readers will no doubt decide for themselves whether the charge is justifiable, but that it is based on a scanty knowledge of how the press works is beyond dispute; the most immediate danger for Nature is that readers will become so bored that they will take to buying some other journal instead. This is one of the reasons why it has now been decided that the present round of correspondence must cease at the end of this month, whether or not the museum has by then chosen to reply to the issues of substance that have been raised.

Nature's role in this controversy is by no means as malevolent as some at the museum suppose. Like any other journal, Nature is to a large extent in the hands of its readers. If people write to say that this or that feature of public policy is mistaken, its first duty is to consider seriously whether what is said deserves a hearing. L. B. Halstead's original complaint that cladism has too great an influence on the museum's exhibition policy (see Nature 288, 208; 1980) is interesting and, if true, important. His further claim that cladism is a cloak for Marxism because Marxist-evolutionists tend to be cladists is illogical (and has been disowned) but is nevertheless an interesting observation even if not strong enough to stand on its own; Halstead will no doubt explain what he meant before the month is out. The most remarkable feature of the correspondence that has occupied the past several months is that it has acquired a life of its own. The original issues have been subsumed in others, while questions have arisen about other matters — the physical arrangement of the museum, for example. From time to tiem, Nature has sought to channel the argument, but not with conspicuous success. The relevance of cladistics to evolutionary studies remains unclear; its place in exhibition policy is a puzzle. The issue of punctuated (as distinct

from gradual) evolution has been raised but not resolved (and cannot be as yet). The status of the theory of evolution — metaphysical or otherwise? — is still disputed, but the museum is probably too agnostic on these questions.

The museum in its public role deserves some sympathy. Nobody should underestimate the difficulties of a public institution in mounting a defence against such a variety of charges. The most obvious difficulty is that the scientific members of this important institution differ among themselves both on the weight they give to this or that aspect of evolutionary theory and also in their opinions of the public exhibition policy. There are now suggestions that some of the criticisms that have been raised in correspondence and by Nature are concealed attacks on individual members of the museum (and Sir Andrew used the phrase "centering around the scientific thinking of members of the museum's staff"). This is not the case. The most controversial member of the staff, the head of the Public Services Division which is responsible for the exhibition policy, is acknowledged to have a flair for work of this kind, and would presumably plough some other furrow with equal skill if the trustees chose to change course. The trustees' problem is to devise a unified policy in circumstances in which the staff of the museum, distinguished as independent scientists, cannot be expected to toe some welldefined line. The museum should soon pay some attention to the problem (which afflicts all public laboratories) of how to marry the need for some coherent outward face with the inevitable diversity of opinion among its staff. The museum, which courageously has not been afraid to amend the most (and

Public but going private

needlessly) tactless part of its newest exhibition, might think of

helping other public institutions to a seemly solution of this

increasingly common problem.

Is the British government about to be still more beastly to the nationalized industries it has reluctantly inherited? There are several signs that this may be the case. Last week, the government decreed that the British Gas Corporation (which has for a year been resisting the proposal that it should cease to be a major retailer of domestic gas-burning equipment) should sell its halfshare in a small onshore oil field in Dorset, evoking the predictable chorus of anguish from the corporation, which is plainly unsure whether it is a public utility or a kind of conglomerate. A more important development has, however, gone comparatively unnoticed. For now, it seems, the British government is bent on making public agencies in the United Kingdom abandon their long-standing belief that their own definition of their own needs should properly take precedence over the needs of their customers in the marketplace. The document put out by the Department of Industry in mid-June, formally a reply to the perceptive report Research and Development for Public Purchasing put out by the Advisory Council for Applied Research and Development more than a year earlier, promises - or threatens - substantial changes in the pattern of British research and development.

The problem is uniquely British. The original report estimated that at least 40 per cent, and perhaps a half, of all applied research and development carried out in the United Kingdom is (or was, in 1975) determined by the needs of British public agencies. The public agencies (government departments, nationalized industries and the research councils) are also eager researchers in their own right; public in-house research and development was running at roughly a third of all British research and development in 1975. A rather greater proportion of defence research and development (some 60 per cent) is put out to private industry on a contract basis than in other fields of the public interest, but this appearance of virtue may be illusory in that the chief beneficiary is the aerospace industry.

The Advisory Council's perceptive complaint, in February 1980, was not that the sums of money involved were too large (which is a different argument) but that government departments

and nationalized industries have wrongly chosen the line of demarcation between themselves and private industry. For, in the most general sense, the objective of most public spending on applied research and development is to define the specification of some product — an aircraft or a repeater in a submarine telephone cable - whose manufacture will afterwards be put out to tender. Manufacturers are always willing enough to put in their bids. Who, after all, wants to turn down business, especially from a customer that can always print the money to pay for what it buys if it cannot otherwise get the funds? The snag, and the chief conclusion of the Advisory Council's report, is that in the cosy relationship that grows up between a paternalistic public sector, willing to shoulder all the cost of research and development itself, and would-be suppliers, scant regard is paid to the long-term interests of the public contractors. Too little of what they make for British government agencies will sell easily elsewhere. Too little of what they spend on research and development goes on the improvement of products that will sell in the wider marketplace.

The Advisory Council's analysis is by no means new. In the 1960s, after a long period of an over-cosy and restrictive relationship with the British Post Office, even the suppliers of telecommunications equipment came to appreciate that the benefits were illusory (yet not a lot has changed since then). The novelty of last year's report was that it advocated a few simple rules of thumb for distributing the balance of research and development between public customers and private contractors. Government and other public agencies have a proper right, even a duty, to carry out research suggesting ways in which the character of their operations may be improved or ways of improving or monitoring the conduct of their existing operations, in matters such as safety. On the other hand, if goods and services are likely primarily to sell to other public customers, the supplier should carry out the necessary research, perhaps with some public help. In intermediate cases, public and private responsibility for research and development should be shared. In general, more publicly supported research and development should be contracted out to private industry.

Rarely can a government's reply to the report of an advisory committee have been as fulsome. With a few justifiable quibbles (where the government is anxious to avoid robbing nationalized industries of their formal autonomy), all the principal recommendations are enthusiastically endorsed. Three government departments (including that for defence, the biggest spender) are said already to have decided to put out more of their research and development. Now the nationalized industries are to be asked to follow suit, but also to find ways in which their own research establishments can sell services overseas. So is a new day dawning for applied research and development in Britain?

The government's enthusiasm is accounted for by its ideology. For months (it seems like years) the government has been talking about "privatization". The Advisory Council's arguments are more objective and thus more persuasive. But everything depends on how effectively the new prescription is carried out. Here doubt persists. The government is probably right not to follow the Advisory Council in the suggestion that there should be an independent board to supervise the fashioning of a new relationship between the public and private sectors in every nationalized industry, but the result will be that final decisions will be made within government departments all too comfortable with past relationships. Conscious as many of the departments will be of the difficulties of managing a substantial shift of resources (for their own laboratories for example) the departments will draw the new lines of demarcation cautiously. This is the respect in which both the original recommendations and the British government's response are inadequate. If the balance of research and development between the public and private sectors is to be shifted substantially, there needs to be some way of anticipating the problems that will arise (such as those afflicting the 75,000 or so people on the government's own research payroll). And there needs also to be, for this purpose and others, some means of letting ministers and taxpayers know what is happening, or about to happen.

White-hot technology lives on in France

New minister plans great leap forward

Paris, June

Part of the mystique of the new Socialist government in France is its almost religious attitude to science, which has startled those on the left who are habitually critical of modern technology. Thus the left-wing daily Libération last week described the Minister of State for Science, Jean-Pierre Chevènement, as a man who embraced growth for growth's sake and sought Soviet-style state control of science. There was no room in Chevènement's policies, said Libération, for the ecological movement or for the debureaucratization, demilitarization and democratization of science.

This is in part true and part false. Chevenement has lost no time in gathering his powers but he is also calling for greater democracy in science planning going beyond the "democracy of the party faithful". He wants science to be "opened up", but chiefly towards industry. And he is not much interested in the environmentalists. On energy policy he is strongly pro-nuclear. And he will have no control of military science, which absorbs 37 per cent of a total French research and development grant of 50,000 million French francs (£5,000 million).

Chevenement sees science rather in the terms of Mr Harold Wilson's British government of 1964. It is the white heat of the technological revolution in which to forge socialism. Science has an "ethical value", he says, in that "there is no socialism without research". He includes in the term "research" most forms of new knowledge — such as social science, which may see a resurgence.

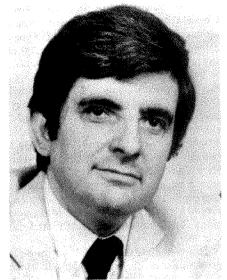

Science in the new government will be expected to help raise the French Gross National Product, to pay for the reconstruction of French society that the Socialist Party has in mind. Some think that an annual growth of 3-4 per cent of the GNP will be needed, compared with 0-1 per cent at present, whence Chevènement's interest in links between science and industry.

During the interregnum, Chevènement battled for weeks with Pierre Joxe, then Minister of Industry, for control of certain key agencies. In the end he appears to have won, although the relevant decree is not yet signed. Joxe has left the government to head the Socialist Party in the new assembly, and the promised decree should give Chevènement the powers he wants.

Specifically, he wants full control of the

Centre National de la Recherche Scientifique (CNRS), the principal body supporting basic science (including social science and humanities) in France; of the Agence Nationale pour la Valorisation de la Recherche (ANVAR), which primes the innovation pump by seeking ideas in universities and government laboratories and supporting their development in industry; of the Mission Interministerielle pour l'Information Scientifique et Technique (MIDIST), an interministerial agency which seeks to improve the national flow of information on science and technology; and of the Délégation Générale à la Recherche Scientifique et Technique (DGRST), which will perform as his administration.

Chevènement (subject to the decree) has also won power over other research agencies which will remain nominally within their present ministries. He will be in control of their budgets, which gives him effective power over their work but not their appointments — a formula he proposed to save ruffled feathers at the ministries he was plundering. These are the Commissariat à l'Energie Atomique (non-military work only), the Centre National d'Etudes Spatiales and the agricultural, medical, ocean science and overseas development research councils. In total,

Chevenement, ready to go . . .

Chevenement will control directly a budget approaching FF 20,000 million.

If the government can hold to its election promises, this budget should rise by some 10 per cent a year until 1985; and by means of low interest loans to industry for research and development projects, the FF 30,000 million industrial sector is planned to rise at the same rate.

For the moment. Chevenement -

Universities jeopardize German budget

A row in West Germany over the funding of new university buildings culminated last week in the rejection of the entire federal budget for 1981. The Bundesrat, the upper chamber of the parliament whose members are the presidents of the eleven Länder, threw out the budget approved on 6 June by the Bundestag, the lower house, on the grounds that it makes insufficient provision for new construction in universities. It was the first time since 1963 that the Bundesrat has overruled the Bundestag-approved budget.

The majority of Länder governments claim that by allocating only DM 680 million for university construction in 1981, compared with the DM 850 million originally planned, the federal government is reneging on its constitutional obligation to meet half of the costs with the Länder. The Bundesrat says that the reduced sum is not enough to pay for projects already under way, let alone for embarking on new ones. Herr Albrecht, president of the Bundesrat, is said to believe that a figure nearer DM 1,300 million is needed if the universities are to expand to meet rising demand. So great is the sense of grievance of the Länder governments that they are claiming that the Bundestag has violated a basic constitutional law - which states that the costs of construction should be shared equally between the Länder and the federal government — and they are taking their case to the constitutional court.

The matter has also been referred to an arbitration committee which is due to meet next week. An earlier attempt at compromise, which would have guaranteed the Länder reimbursement after 1984 for extra money spent in 1981, failed. But it is now hoped that the Länder will agree to accept reimbursement of DM 120 million in 1982 and the remaining DM 50 million in 1983.

Until this year, cuts in the West German federal budget were practically unheard of. But the worsening economy has forced the government to look for savings. The Länder have used the constitutional obligation on university construction funds to challenge the government's plans for savings and are said to favour cuts in agencies with large bureaucracies such as those dealing with employment and social security.

West Germany has been expanding its universities since the early 1970s and has already spent DM 25,000 million, mainly on upgrading technical colleges to university status. The plan is to invest another DM 20,000 million if the economy can stand it.

The recurrent grant to universities, which is paid by the local Länder governments, is not involved in the dispute.

Judy Redfearn

assuming the decree is forthcoming — has three targets.

First, there is an adjustment to the 1981 national budget, due in July. Here Chevenement does not expect much money, but he has promised 525 new research jobs among his agencies, 200 of them for scientists (the rest for technicians). In the agencies over which he has full control (such as CNRS) he will favour the social sciences, basic biology, medical sciences and (surprisingly) environmental science.

Second, there is the full 1982 research budget, to be fixed in August this year. Here Chevenement plans the full 10 per cent growth, in real terms, and plans to make biotechnology, microelectronics and robotics priority subjects, and to support ailing but important subjects such as chemistry.

Third, in 1982 he will seek a "loi de la programmation de la recherche", in which the National Assembly would vote a firm five-year plan and budget within which his ministry could operate without fear of political setback year to year. Such a "loi programme" has not been tried before outside defence, and it will be a supreme test of Chevènement's undoubted political powers to get such a law approved.

To that end, he is calling a national colloquium of scientists and others interested in science policy for December this year, to thrash out a "new politics" for science and rally support. Robert Walgate

US science research

Keyworth reassures

Washington

In his first public appearance since being nominated as President Reagan's Science Advisor and director of the Office of Science and Technology Policy, Dr George A. Keyworth II said last week that the new Administration "views basic research as a vital investment with a good return", that it would seek to increase industry's involvement in research and development and that greater international collaboration was essential in such capital-intensive fields as high-energy physics and space research.

On a less positive note, he warned that the United States could no longer expect to dominate research in all scientific disciplines and should accept that "our country has relinquished its pre-eminence in some scientific fields". He also stressed that support for research should be aimed primarily at those areas considered important for industrial, military or other essential technologies, or where efforts were proving particularly productive, such as computer science and genetic engineering.

Dr Keyworth's remarks were made in a speech to a meeting organized by the American Association for the Advancement of Science (AAAS) to discuss recent trends in the federal research and develop-

ment budget. Many of those present were impressed that although Dr Keyworth, a 41-year-old nuclear physicist who has spent most of his career at the Los Alamos Scientific Laboratory, has virtually no experience of Washington science policy circles, his remarks demonstrated a grasp of many of the issues facing the Administration.

Asked about attempts by the Office of Management and Budget to apply strict cost-accounting procedures to university scientists, for example, Dr Keyworth replied that he himself had never been required to punch a time-clock, but that there were arguments about public accountability that needed to be closely considered. He also expressed concern at the possible damage to international relationships that might follow budget-based decisions to withdraw from projects such as the International Solar Polar Mission, being planned jointly with the European Space Agency.

In his speech, Dr Keyworth emphasized that he saw his role as an "objective adviser" in the White House rather than an inside lobbyist for the engineering and scientific communities. "The Science Advisor in this Administration perhaps more than in any other will be an important member of a *team* of domestic and international advisers", he added.

The content of his speech made it clear that Dr Keyworth is likely to pursue many of the same goals as his predecessor, Dr Frank Press. Referring to the need to reduce the burden of "unnecessary" regulation on the private sector, he said that the Office of Science and Technology Policy would continue to work closely with others in the Administration to strengthen the scientific foundation of federal regulatory decision-making.

However, Dr Keyworth, who has been closely involved in nuclear weapons research at Los Alamos, said he believes that "our country's military might should be second to none", and has also been reported as saying that within the new Administration "science and engineering that support the development of a stronger defence have top priority."

In previous administrations such remarks might have been taken as a warning signal by the biomedical research community. But the commercial potential of genetic engineering, being a rapidly expanding field of high technology, seems to have kept such research in favour. "In general, I think we will see continued strong support for the biological and biomedical sciences", Dr Keyworth said.

Other speakers from the Administration who addressed the AAAS meeting supported the contention that basic science had little to fear from Mr Reagan, and that cuts in the research and development budget were intended to fall primarily in those areas where private industry might shoulder responsibility.

Many of those attending the conference,

however, were not totally convinced. Several questions were raised about the Administration's proposal to eliminate science education programmes at the National Science Foundation (some of which appear to have been salvaged by Congress). Others, such as Dr Ronald W. Lamont-Havers, director of research policy at the Massachusetts General Hospital, expressed concern that even though the Administration might believe in the need to support scientific excellence, budget constraints on research funding were likely to result in high-quality research not receiving adequate federal backing.

David Dickson

EEC university qualifications

Degree of agreement

Brussels

Education ministers from the European Community's ten member states, meeting in Luxembourg in June, considered the tricky problem of improving the mutual recognition of diplomas and periods of study undertaken at higher education institutes.

In theory the principle of the freedom of employment set out in the Treaty of Rome should guarantee that a qualification gained in one member state should open the same economic doors in another state, but this is far from being the case. As one example, a teacher with a degree from the University of Lille who spent her working life in Belgium was not granted her full pension rights because the Belgian state did not recognize her qualification.

No one has been foolhardy enough this time to suggest establishing a Euro-degree on the lines of the much-maligned Euroloaf or Euro-beer. The low-key approach adopted by the European Commission is to improve the availability of information. EURYDICE, the European information network on education which became operational last year, would link up with national units to provide information in five key areas - entry requirements for first degrees, transfer without loss of acquired rights from a course started in one country to a similar course in another member country, requirements for postgraduate studies or research in another member state, finding work in a member state with qualifications obtained in another, and details of career development.

The Education Council has approved these ideas and the Commission has until March 1982, when the education ministers meet again, to put forward some precise ideas on implementing the scheme.

But this leaves the crucial problem untouched. Should the Community risk an outcry from the academic world by forcing universities to accredit each others' degrees with the same value and worth? Desirable though that would be as a means of increasing the mobility of European academics, it would ride roughshod over the treasured traditions and autonomy of the institutions.

As a principle or ideal it was welcomed by the ministers and has few opponents in the academic world. The difficulty is that the Education Council realized that the edict cannot be enforced by law. Efforts over the past twenty years to encourage bilateral or multilateral agreements have not kept pace with the growth of higher education and diplomas. The Commission has now been instructed to persevere in its efforts to find ways of encouraging more agreements.

Jasper Becker

High-energy physics

CERN in a hole

The Large Electron Positron ring (LEP), the future project of the European centre for subnuclear research (CERN) near Geneva, has run foul of a small group of environmentalists formed a decade or two ago to protect the Jura Mountains, north of the CERN site, as a national park. Last week the group obtained an injunction at a Lyon tribunal which annuls CERN's licence to bore an exploration gallery for the LEP tunnel into the Jura.

The Lyon decision rests on a technicality. It stipulates that the exploration gallery is not a "temporary construction", as it must be according to the law under which CERN began drilling, but a permanent one. CERN counters that if the tunnel revealed that the construction of LEP would be impossible, then the work would indeed be temporary. However, CERN intends to use the 4 km tunnel as an entrance gallery if LEP goes ahead — so their position was not too strong.

Meanwhile, CERN has not been informed officially of the injunction. Being an international organization, its relations with states — including Switzerland and France — on whose territory it rests, are mediated through the foreign ministers of those states; and there will now be an internal wrangle in France either to get the Lyon decision overruled, or to gain approval for the gallery under another law.

The conservationists, the Association de Protection de la Nature Gessienne (that is, of the Pays de Gex where the gallery was to be drilled), are worried about potential damage to natural springs in the region, and atmospheric pollution from LEP power supplies and cooling systems.

The group timed its injunction well: it coincided with the mid-year CERN council meeting at which national positions on the LEP project were being sounded. In the event, the French delegate at the council, M. Yves Jacques, promised to appeal against the Lyon decision at the highest court — the Conseil d'Etat — and the voting was as previously expected: eight clearly in favour and four undecided. Of

the latter, Denmark expects parliamentary approval soon; after a confusing general election, the Netherlands wishes to delay a decision; Sweden is in similar position after the collapse of the Conservative government; and Norway wishes to wait until after its general election on 14 September.

A committee of the CERN council is to meet in October, and if member states are then ready, a full meeting could be convened to reach the unanimous approval that CERN seeks. (Strictly the eight-tofour majority is sufficient, as LEP will come within the normal CERN budget; but unanimity on such a big commitment more than SF 600 million (£150 million) for five years or more - is thought politic.) At that final meeting, which could be delayed to December, the central issue is likely to be not whether the states all approve of LEP, but at what budget they want it built which affects the speed of LEP construction. Argument on the budget was heated in the meeting last week, and no agreement was reached. Robert Walgate

Polish economy

Culling ministries

The Polish government's plans for economic recovery will be based on a major restructuring of the country's production ministries, Prime Minister Jaruzelski announced in the Sejm (parliament) recently. During the past few years, there has been a tendency for Polish ministries to proliferate - for example, separate ministries for the metallurgical industry, for the engineering industry, and for heavy and agricultural machinery existed at the same time. Even during the past few weeks, there have been suggestions that some of Poland's most urgent problems, environmental protection and geological surveying among others, could best be tackled by creating new ministries.

The new plan proposes replacing ten existing ministries with four larger ones. These four would cover agriculture, food procurement and production, and forestry; mining of coal and lignite and energy production; heavy industry and machine construction; and chemical processing of timber, natural and artificial fibres, and the ceramics, glass, cellulose and paper industries.

General Jaruzelski went on to remind the Sejm of some of the mistakes of past years, when separating the mining industries from power production, and machine building from foundry production caused serious losses in productivity.

The new proposals have not met with unqualified approval. The Sejm Commission for Forestry and the Timber Industry is unhappy at combining forestry with agriculture, but the corresponding commission dealing with agriculture and the food industry seems fairly happy with the union.

Vera Rich

US standards bureau

Wider horizons

Washington

The US National Bureau of Standards, traditionally a preserve of the physical and engineering sciences, is being asked by a congressional committee to broaden its horizons and take on responsibility for the burgeoning field of biotechnology. The recommendation is one of several being put to the bureau as a way of "enhancing the technological and scientific base of the nation's industrial capability".

There has been little reaction yet from the Reagan Administration to the proposals, which have been drafted by the science, research and technology subcommittee of the House Committee on Science and Technology. Secretary of Commerce Malcolm Baldridge told the committee at a hearing in Washington last week that the whole internal organization of his department, which is responsible for National Bureau of Standards, is under review. He talked of an important role for the bureau - in helping to boost US exports by providing data about foreign product standards but said it was too soon to be specific about changes.

The changes being proposed are in line with the findings of recent studies of the bureau, including reports from the General Accounting Office and the Congressional Research Service. In addition to its traditional responsibilities for weights and measures, several committee members, including chairman Doug Walgren, are convinced that the standards bureau could have a central role in federal efforts to stimulate technological innovation in the private sector.

The bureau's principal responsibility has been to help ensure the compatibility of measurement standards needed by industry, consumers, the scientific community and other organizations. In recent years Congress has given the bureau various additional functions, such as administering the Center for Fire Research and the Center for Consumer Product Technology. But often the bureau has been given a new role without adequate funding with the result that other programmes, have been cut back or eliminated.

Last year both the Senate and the House of Representatives held authorization hearings on the bureau's budget to explore possible remedies. Now the House committee is drafting a bill making the bureau's responsibilities more explicit, but also intended to enlarge its contact with the broader research community.

Many of the committee's suggestions are uncontroversial. There is general agreement that adding the biological to the physical sciences would be appropriate, in particular in the development of standards, testing procedures and measurement instrumentation needed for the advancement of biotechnology and genetic

engineering, although there is concern that the changes should not go too far for fear of conflict with work already being carried out by the National Institutes of Health.

There is widespread support for a proposed amendment that would require the National Bureau of Standards to engage in international cooperation, and that it should maintain measurement research and development as its top priority. The bureau's director, Dr Ernest Ambler, welcomed the committee's recommendation that any new new functions should be provided with adequate funds and manpower.

The committee's suggestion that the bureau be given authority to promote economic growth by "contributing to the development of the basic technologies which underlie product and process development, technological innovation and productivity" raises greater difficulties. Although the bureau does at present support research aimed at the general enhancement of industrial innovation—for example in computers or machine tools—these are undertaken only when they can be shown to be measurement-related. Members of the committee argue, however, that in practice

Support for Argentinian

Leblon, Brazil

Professor Nicolas G. Bazan, sacked in controversial circumstances as director of the Biochemical Research Institute of the University of the South in Bahia Blanca, Argentina (Nature 14 May, p.100), was greeted enthusiastically at a symposium last month organized by the Argentinian Academy of Sciences in the city of Córdoba.

Several of the foreign biologists invited to the symposium, on molecular aspects of the nervous system and memory, carried letters from their professional societies protesting against the dismissal of Bazan and the continued arbitrary attacks by the Argentinian government on scientists. Among them were letters from the American Society of Neurochemistry and from the European Society of Neurochemistry and from the European Society of Neurochemistry. In spite of the risks of reprisals, the Argentinian academy publicly endorsed these protests from the international scientific community.

Bazan has been invited to visit the United Kingdom to attend the forthcoming biannual meeting of the International Society for Neurochemistry in Nottingham next September, where a special symposium on the human rights issue in Latin America is being planned. It will deal in particular with the situation of the several hundred Argentinian scientists who are reported as "disappeared". "arrested" or "summarily dismissed".

Maurice Bazin

the bureau already seems to be stretching its definition of measurement in some of the research that it supports. If the organization feels it is limited by the terms of its existing statute, then the solution, they argue, is merely to change the wording of the legislation.

Several witnesses at last week's hearing felt the bureau could have the wider role envisaged in the proposed legislation. It would unduly limit the potential value of the bureau to the nation if its only activities were in the field of metrology.

The committee suggests that the bureau strengthen its links with the academic community by being allowed to make grants and to award fellowships in science and engineering. But Mr William Carey executive officer of the American Association for the Advancement of Science and until recently chairman of the bureau's board of visitors, warned against this on the grounds that "the granting business these days is bogged down with rules and controls for fiscal accountability" and that "adding another granting agency to the confusion would be regrettable".

How far the committee's recommendations go will depend greatly on how far they agree with the Department of Commerce's own views. Mr Baldridge has already eliminated the position of assistant secretary for science and technology, the post previously occupied by Dr Jordan Baruch, a principal author of President Carter's domestic policy review on industrial innovation. Upgrading the National Bureau of Standards would be one way of filling the resulting gap.

David Dickson

India in space

Another orbit

Lucknow

India's latest venture into space was the launch of the experimental telecommunications satellite, Apple, aboard the third Ariane test flight last month. Apple is unlikely to prove as successful as the Indian Space Research Organisation must have hoped after one of the two solar panels failed to deploy shortly after launch. But there is a chance that such a small satellite, 616 kilogrammes, can operate satisfactorily with one solar panel for long enough for the bulk of the experimental work to be done.

The Apple programme is only one of the fronts on which India is advancing into space. At the end of May, as part of the first developmental flight of its satellite launch vehicle SLV-3, India placed a 38-kilogramme satellite into a low Earth orbit. That was the second satellite to be put into orbit using the Indian rocket, the first having been launched last July (Nature 286, 324; 1980).

The latest Indian-launched satellite, designated RS-DI, carried a solid-state

sensor capable of identifying salient features on the Earth and transmitting data back to the ground stations.

The main objective of the Apple satellite launched on Ariane but built at the Space Application Centre in Ahmedabad, is to gain experience in the operation and management of communications satellites. Yet another satellite, Bhaskara II, is due for launch at the end of the year and is for the development of remote sensing technology.

Experiments planned for Apple include logging the movements of railway wagons and of railway passenger reservations in large cities, the setting up of an interlibrary information system and the development of a "national classroom" for postgraduate engineering students at the five Indian Institutes of Technology. Under the last programme, students at the five centres will be given televised lectures and be able to question the lecturers directly.

Zaka Imam

Occupational health

US industry to pay

Washington

In a decision that represents a victory for the US labour movement and a major blow to the Reagan Administration's efforts to reduce the burden of health and safety regulations on private industry, the US Supreme Court has ruled that the Department of Labor's Occupational Safety and Health Administration (OSHA) is not required to carry out rigorous costbenefit analyses of new regulations covering exposure to toxic substances before the rules are put into effect.

The drive to put occupational safety and environmental regulations on a strictly cost-benefit footing has been central to the new Administration's 'regulatory reform' strategy. In line with this, the head of OSHA, Mr Thorne Auchter, asked the Supreme Court in March to delay a decision on whether regulations introduced by the Carter Administration in 1978 to reduce workers' exposure to cotton dust were invalid since they had not been accompanied by a thorough analysis of the relative costs and benefits.

However, the court has turned a deaf ear to the agency's request. In a move that will now require both OSHA and the White House to ask for new legislation from Congress if it wants to pursue the strategy, the court ruled by five votes to three, with one abstention, that there is nothing in the law to require such analysis. Rather it has accepted the interpretation of OSHA officials under the previous administration, that the mandate requires the agency to do all it can to reduce health hazards to workers, short of bankrupting the industry concerned.

The new cotton dust regulations, which are already being implemented by most large textile manufacturers, are aimed at

lowering the incidence of byssinosis (brown lung disease) among the nation's 800,000 textile workers. In 1978 OSHA issued regulations requiring the permissible level of cotton dust to which workers could be exposed to be reduced from 1,000 to 200 microgrammes per cubic metre of air.

Even at the time the ruling was highly controversial. Whereas OSHA officials estimated that the cost of compliance to industry would be about \$650 million, industry itself put the figure at \$2,700 million.

The Supreme Court's decision is the final step in a legal challenge launched by the American Textile Manufacturers Association, asking that the rules be disregarded because the agency had not demonstrated that the expected benefits outweighed the likely costs of implementation. If the appeal had been sustained, it would have allowed the Administration to proceed relatively unimpeded with its plan to apply strict cost-benefit analysis to various regulations already in effect — for example those covering exposure to arsenic and lead — with a view to reducing their severity.

This strategy will have to be reassessed, now that the Supreme Court, in a ruling by Justice William J. Brennan, has concluded that OSHA is not required to carry out such an analysis, but merely to determine that its regulations are technically and economically feasible.

Although professing to welcome the justices' verdict, since it formally supports the government's position, OSHA officials also acknowledge that it is a set-back to their attempts to chart a new course for the agency that would be more congenial to private industry. Mr Auchter has already made clear his strong disagreement with the philosophy and policies of his predecessor, Dr Eula Bingham.

Predictably the court's verdict has been warmly welcomed by labour unions representing textile workers, but their jubilation may be premature. Already OSHA officials have revised their approach to new regulations in the light of last July's ruling by the Supreme Court, in rejecting proposed new standards for exposure to benzene (Nature 286, 97; 1980). And following the cotton dust decision, a spokesman for the textile manufacturers said that the companies "continue to believe, as does the Administration, that cost-benefit analysis is an important element in achieving rational and costeffective rule-making'

But much of the fire has disappeared from the textile industry's complaints, Many companies acknowledge that their calculations of likely costs were based on the conversion of old equipment and that new regulations have led them to buy new machines that have already produced significant gains in profitability. It is a silver lining that few would have expected when the regulations were hailed as a large black cloud over the industry

David Dickson

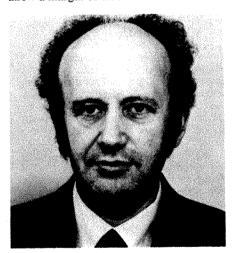

Dietary vitamin C

Bigger daily dose?

Britain's answer to Linus Pauling now argues that the government should raise the recommended daily amount of vitamin C from 30 mg to 100 mg—enough to saturate body tissues with the vitamin, but nowhere near the "megadose" levels Pauling advocates.

The new British "Mr Vitamin C" is a mild-mannered Welshman, Dr R. Elwyn Hughes of the University of Wales Institute of Science and Technology. His book on the subject has just been launched by the British Nutrition Foundation, which though supported entirely by the food industry is at pains to provide "balanced" information on nutritional matters. The foundation supports Dr Hughes's recommendation that the government should reassess the criteria by which recommended daily amounts are arrived at, but makes no commitment to the actual level of vitamin C we need. On this Dr Hughes — officially — stands alone.

We owe the British recommended amounts to a group of conscientious objectors who in 1940 were subjected to zero vitamin C diets. They soon showed the symptoms of scurvy, and their intake of vitamin C was raised slowly until the scurvy disappeared. It disappeared at 10 mg a day; so the government tripled this amount to allow a margin of error.

Britain's Pauling?

However, the past decade has seen the discovery of useful functions for vitamin C other than just preventing scurvy, says Dr Hughes, such as involvement in lipid metabolism and atherogenesis; brain metabolism; carnitine metabolism (which relates to muscle fatigue and lack of stamina); resistance to infection; and the detoxification of potentially harmful drugs, including certain tranquillizers. Although such evidence is incomplete it is sufficient to commend tissue saturation levels of the vitamin, he concludes.

According to British dieticians, the average daily intake of vitamin C in the United Kingdom is 60 mg, equivalent to the

content of two fresh oranges, But many people take much less. In a survey of old people's homes in South Wales, Dr Hughes discovered average intakes of less than 20 mg, and in some cases less than 10 mg.

Dr Hughes does not recommend megadosage, however. Its benefits are unproved, he says. Half of any excess over saturation is swept out in the faeces, and the rest rapidly in the urine; and moreover there is evidence of disadvantage, in particular that toxic metals can be forced across the placental membrane by high vitamin C fluxes.

Robert Walgate

Soviet mineral supplies

Digging deeper

Talk in the West of a "resource war" between the Soviet Union and the United States seems to have prompted a reaction from the Soviet Minister of Geology, Evgenii Kozlovskii. Talking on Radio Moscow, he said that speculation that the Soviet Union would soon become a net importer of mineral ores was mere Western propaganda.

The minister's statements may have been a response to the recent meeting of geologists and Soviet watchers at the Johns Hopkins University (see Nature 11 June, p.444), which concluded that while there was little evidence to support the view of some of President Reagan's more "hawkish" advisers that the Soviet Union was deliberately waging a resource war, there did appear to be production difficulties in the Soviet Union leading to a cutback in mineral exports and the stepping up of imports.

According to Kozlovskii, the Soviet Union can not only meet its own mineral requirements, but also has surpluses for export. Although his assertion that the Soviet Union has the world's largest known deposits of coal, gas, iron, manganese and apatite is probably true, it does not follow that sufficient supplies are available to Soviet industry.

At present, apparently, Soviet geologists are discovering new mineral deposits faster than the mining engineers can extract them. But there is still great emphasis on new methods of surveying for minerals, including satellite surveys and the drilling of deep and "super-deep" boreholes.

Deep boreholes, in fact, are to play a big part in Soviet geophysical research in the 1980s. The first such hole, on the Kola peninsula, reached a depth of 10,800 metres and a new hole to be drilled in Western Siberia is thought to be of particular significance because of hopes of finding oil deposits in Pre-Jurassic strata at depths of between 5,000 and 7,000 metres. Even deeper drillings are being planned, to depths of greater than 13,000 metres, where high ambient temperatures (up to 350°C) and high pressures will require new drilling techniques and monitoring Vera Rich instruments.

CORRESPONDENCE

Defence for Chelsea

SIR — Your correspondent, in summarizing the recommendations of the Committee on Academic Organisation of London University, has failed to comment on an alarming feature of the discussion document. The committee state that their judgements on academic standards in institutions are based on "general reputation" and their own personal opinions. It is on this basis that it is implied that the majority of departments at Chelsea College are not of the standard of the university at all. How else can those who survive the proposed "peer review" be accommodated on a "single site", given the present size of the college?

The University of London is a great, but complex, institution. It faces brutal cuts in funding over an alarmingly short period of time and it was thus wise to have set up the Committee on Academic Organisation under Sir Peter Swinnerton-Dyer to assess the implications of the expected cuts and advise on their implementation with minimal damage to academic standards. But the committee has yielded to the temptation of extrapolating objective financial analysis into arbitrary recommendations based on subjective and highly damaging prejudgements. Instead of setting the scene for cooperative rationalization and contraction, the document has generated anger and dissention.

The committee had already clearly established that for years the sub-allocation of the UGC block grant to London by the Court of the University has favoured certain colleges at the expense of others. Inevitably, the high unit-cost colleges, with their favourable facilities and staff ratios, have tended to attract more research grant monies than have the low unit-cost colleges. Nevertheless, and in spite of the conditions under which they have been forced to operate, the under-provided schools have not only become better integrated and more innovative than the giants, but contain many departments of true distinction.

Yet the committee's conclusion is that it is "unthinkable" that the necessary savings should be made where the high costs have been identified. Instead, the worst of the burden is to fall on colleges that, having been starved from the centre, are now judged, a priori, not to be academically excellent — as if, in any case, excellence can ever be ascribed to a college rather than to individual departments.

Chelsea College has survived a succession of externally-engineered crises, and in the face of them has grown from strength to strength. Operating at exceptionally low unit-costs we still have built up departments that are among the biggest and best of their kind in the university, and some of which have a major international reputation. Why then have we been singled out for gratuitous attack? Is it simply and cynically that we are a sitting target, fully-stretched financially and spatially, and big enough if destroyed to spare others their share of the agony?

A simple way to destroy a college is to malign its reputation, so that potential students and benefactors and the various grant-giving bodies shy away. If this is not what the committee consciously set out to do, then the publication of the discussion document represents a sad error of judgment.

The attack on academic standards at Chelsea College not only offends us, it insults boards of studies of the university and its external examiners, jointly charged with maintaining standards in their subjects. They are, by implication, accused of incompetence.

The committee should now retract their scenarios and their gratuitous insults to Chelsea and to the other colleges judged to be "weak", and leave the schools themselves voluntarily to suggest rationalization within objectively defined guidelines. Otherwise, the university should forthrightly reject as incompetent the latter part of the report.

Postdocs are OK

SIR — I object strongly to your comments regarding the future for postdoctoral fellows in the United States (*Nature* 11 June, p.441). The 50 per cent increase in postdoctoral grants since 1972 represents an expansion of the equality of opportunity for recent graduates, and the federal policy-makers responsible ought to be applauded, rather than attacked with words like "demeaning employment", "exploited", and "scandal". You confuse an equality of *opportunity* with an equality of *outcome*. Sadly, this is a common confusion that muddies the minds of the liberal thinkers of both our peoples, and breeds frustration amongst the unfortunate victims that subscribe to their thought.

The value of postdoctoral study and its "prize" of an academic post remain intact ("88 per cent of the most recently appointed assistant professors in chemistry had done a postdoctoral stint" etc., p.443). For many, this study is preceded by an overkill of classroom exercises and examinations, and followed by endless faculty committee meetings and governmental paperwork, leaving only those precious postdoctoral years where one can devote full time to research, and attempt to achieve the scholastic maturity necessary for undertaking truly independent investigations. (Incidentally, independence is the mark of a "professional", not the social status, health insurance, or salary implied by your comments and the juvenile anecdotes of the disappointed. Anything less denotes hired help, regardless of training, qualification, or special ability.) The statistics of the Grodzins Committee fail to take into account those students of highest ability and fortune who achieve this maturity while earning their degree (all are supposed to) and therefore do not need a postdoctoral period of additional opportunity. For the remaining majority, it stands to reason that an increase in the numbers electing to enter this race for a fixed number of prizes will be followed by an increase in the numbers who do not win. Is that so surprising as to deserve front page coverage? Is it morally offensive? Is it indicative of someone in authority having failed in their responsibility, as you state? I think not. You propose that those who do not win "should be paid a bounty, a kind of retrospective recompense for deprivations" Now that I do find morally offensive, lying somewhere between race-fixing and squandering public money on a losing proposition, or to be blunt, on losers.

Dexter B. Northrop University of Wisconsin-Madison, USA

Cox sure?

SIR — Barry Cox's comments on the British Museum (Natural History) exhibit on Origin of Species (*Nature* 4 June, p.373) contain an incredible statement which must not pass without challenge. Otherwise, the creationists' claim that evolutionary science is really dogma will have received the *imprimatur* of your journal. The statement is:

"We [biologists] don't even think that it [the evidence] could support a dramatically different scientific (sic) theory, in the way that earlier observations of the heavens were transformed from being compatible with an Earth-centred Universe to demonstrating a Sun-centred Solar System."

As a practising biologist, I wish to register my dissent. Surely, Dr Cox got carried away. Does he understand the implications of novel findings in genetics so completely that he can make such a statement with serenity? Is it certain that new data on genome organization and variation will not lead to fundamentally new ideas about the mechanisms of speciation? Have we fully assimilated the lessons of overlapping and interrupted coding sequences, mobile genetic elements, and somatic differentiation by chromosome rearrangements? With all due respect to Dr Cox and the many scientists who believe that the problem of evolution is solved "in principle", let me state my conviction that there is a great deal of aptness in the analogy between Ptolemaic astronomy and our current understanding of evolution.

JAMES A. SHAPIRO Department of Microbiology, University of Chicago, Illinois, USA

Fit for what?

Sir - In his article (Nature 4 June, p.373) on the new Origin of Species exhibition in the British Museum (Natural History), Dr Cox quotes the sound track of a film loop "The Survival of the Fittest is an empty phrase, it is a play on words". This appears to refer to the widespread belief that "survival of the fittest" is a tautology, because our only measure of the fitness of an organism is its ability to survive. This is not so; in the long run survival is a problem for palaeontology, because fossils are our only evidence of what has failed to survive. And in palaeontology, there is a technique which can be used to estimate fitness (in the ordinary dictionary sense). This uses the "paradigm" method developed by Rudwick¹ for testing functions inferred from structures in fossils. The structure concerned is compared with a paradigm which is the ideal for the performance of that function (due allowance being made for the nature of animal materials). Paul² has taken this farther, and compared with the appropriate paradigms a series of structures which perform the same functions in different primitive echinoderms. He concluded that, for the functions of protection, feeding and respiration, the echinoderms of the Cambrian and Ordovician were less efficient than their successors. Moreover, this was compatible with the elimination of the unfit by competition (which is "survival of the fittest" in reverse).

NEWS AND VIEWS

Modern light microscopy

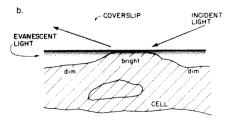

from Michael Spencer

New techniques in electron microscopy have over the years been matched by innovations in light microscopy, which retains the unique advantage of being applicable to living cells. Two recent papers illustrate this well, and also emphasize that in several respects the conventional formula for the resolving power of a light microscope may be said to underestimate the potential of the instrument.

The first, by Daniel Axelrod (J. Cell Biol. 89; 141, 1981), is about a new application to microscopy of total internal reflection fluorescence (TIRF), a branch of spectroscopy dating from the sixties. It complements another existing technique (also introduced about twenty years ago) called interference reflection microscopy, which can show up cell-substrate contacts as darker regions against a background of light reflected from other areas of cell surface. In the case of TIRF, however, the opposite situation applies: only the contact areas give rise to light collected by the objective.

Light from a laser (Fig. 1) enters a glass or fused quartz cube at such an angle that it undergoes total internal reflection at the interface between a glass coverslip and a film of medium containing cultured cells. The cell membranes have previously been 'doped' with a fluorescent label. Although geometrical optics predicts no transmission of light across the interface, electro-

COVERSLIP

magnetic theory shows that a disturbance which Axelrod calls an evanescent wave (a term taken from diffraction theory) will penetrate into the liquid medium. This wave propagates parallel to the surface with an intensity that decays exponentially with perpendicular distance from the interface; although in the ideal theoretical case no energy crosses the boundary, many observers (from Newton onwards) have shown that this is not true in practice. Within a thin layer adjacent to the interface, fluorescent molecules can be excited by the evanescent wave.

The depth d at which the wave's intensity falls to 1/e of the incident value depends on the angle of incidence; the larger this angle, the smaller the value of d. It is possible to arrange that most of the fluorescence is confined to a layer only about 100 nm thick, which is considerably less than the wavelength of the light; even smaller values would be feasible with the use of highrefractive index components. The technique allows membrane-bound receptors, or elements of cytoskeletal structure, to be selectively labelled and shown up without interference from fluorescence arising elsewhere in the specimen. Furthermore, by varying the angle of incidence (and hence the depth of excitation) one can map the topography of the membrane facing the substrate. Figure 1(c) illustrates the kind of picture that is obtained.

The second paper concerns the application of polarizing microscopy to biological systems. Shinya Inoué is the doyen of workers in this field, and has for many years been engaged in pushing the technique to the limits set by current technology. Visitors to the inner sanctum where he conducted some of his experi-

Fig.1 TIRF microscope apparatus for viewing cells in culture. (c) Human skin fibroblasts labelled with a fluorescent marker and illuminated by TIRF. Angle of incidence 74.3°, d = 105 nm. Bar = 30 nm. From Axelrod, D. J. Cell Biol. 89, 141 (1981).

ments were required to exchange their shoes for carpet slippers, lest particles of New England dust should contaminate the optical surfaces and give rise to unwanted scattering. His latest report (*J. Cell Biol.* 89; 346, 1981) concerns the improvements now possible with the use of video image processing.

The most serious problem in observing weakly birefringent objects in a polarizing microscope is that the method is a darkfield one; very little light is collected, and even if the dark-adapted observer sees something clearly, it can require a long photographic exposure to record the image. Furthermore, the background level is raised (and contrast reduced) by polarization effects arising at lens surfaces. Inoué tackled this problem more than twenty years ago and showed that it could he ameliorated by the use of 'rectified optics' incorporating additional elements. However, this still does not enable one to use the highest-quality objectives that are essential for achieving maximum resolution, because these incorporate fluorite lenses that contain crystalline inhomogeneities whose effects cannot be compensated for.

With video recording and reproduction, however, it is simple to subtract an unwanted background level electronically, and thus enhance the contrast. With a highly sensitive video camera one can also

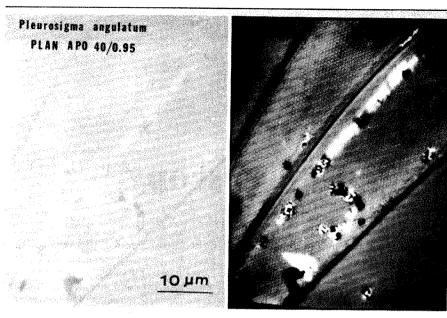

Fig.2 Appearance of a diatom in video-polarized light microscopy, using a plan apochromatic objective. The left scene was adjusted to match that seen by eye through the ocular, while the right scene was electronically adjusted for optimum contrast. The diatom was embedded in a medium of nearly matching refractive index. From Inoué, S. J. Cell Biol. 89, 346 (1981).

reduce the exposure time for photography, so that rapidly moving objects can be followed. Just how striking the improvement can be is illustrated by Fig.2, which compares a diatom as seen by eye through

the microscope with the image photographed from a video system adjusted for optimum contrast. Comparable improvements are also posible in the field of interference contrast microscopy.

Inoué's paper includes pictures, taken by the new technique, of beating cilia, acrosomal processes in the act of extending and rotating bacterial flagella. All of these have diameters much smaller than a wavelength of light. Dark-field photography of sub-microscopic objects is not, of course, new, but the use of polarized light adds new information about the orientation of macromolecules within the structures; in particular, birefringent structures show up without interference from the non-birefringent background. Inoué illustrates this point with a high-resolution picture of the ridges on the surface of an epithelial cell.

He adds a caveat that to get the best results one must take account of the nonideal performance of both optical and video components, and exercise great care in optimizing the illumination. The light levels are so low that by maladjustment one can easily lose the image in a background of instrumental noise. Such problems, and the rival merits of different commercial systems, are the subject of hot debate among the cognoscenti; there is no doubt, however, that future advances in video technology will give further boosts to the older branches of microscopy.

Seabirds and oil: the worst winter

from Chris Mead and Stephen Baillie

LAST winter more oiled seabirds bearing rings were reported to the British ringing office than ever before: a total of 103 birds of ten species from December to March. Many were found in areas where exceptional numbers of dead and dving oiled birds had been counted on beaches (see the figure). A single incident in the Skagerrak accounted for 22 ringed birds and resulted in a total of 30,000 oiled seabirds being found on beaches. Other areas where recoveries of ringed birds were concentrated suffered oil pollution from a variety of sources rather than the acute pollution from a single source experienced on the Skagerrak. The aggregate of beach counts of oiled birds in Western Europe last winter probably approached 60,000 (ref. 1).

The lack of comparative figures from earlier years for counts of beached birds over all the affected areas precludes the use of such counts for annual comparisons. However, details of ringing recoveries for many years are available and allow the scale of the oiling mortality of British populations to be assessed. The worst affected species, the two large auks guillemot (Uria aalge) and razorbill (Alca

Chris Mead and Stephen Baillie are research workers at the British Trust for Ornithology,

torda), spend a large part of their time swimming and are therefore likely to encounter floating oil^{2,3}. These two species accounted for 84 per cent of the oiled ringed birds. Information on the numbers of ringed birds at risk and numbers recovered from last winter and 1967-68 to 1978-79 is given in the table. This shows that guillemots experienced four times as much oiling as usual and razorbills about three times as much. For guillemot, but not for razorbill, more birds were also 'found dead' than usual. These figures conceal some age-related differences between the two species. For guillemot the youngest birds were worst affected (4.5-fold mortality increase) with immatures suffering a 2.3-fold increase but adults only 1.4 times normal mortality. For razorbills only adults were badly affected (2.5-fold increase in mortality) with younger birds surviving as well as or better than normal. These results reflect the species' different migration patterns4-6: most sub-adult razorbills winter well south of the areas of oiling and adult guillemots mostly winter close to the breeding areas which were unaffected by oil.

Although several thousands of each species are marked each year, the ringing effort is not uniformly distributed throughout the birds' breeding range in

Britain and Ireland. There are four areas where it is possible to speculate about the effect of the 1980-81 mortality of guillemots: Orkney and Shetland, Grampian region, north-west Scotland and Saltee, Co. Wexford. If there is no compensatory increase in the survival of the remaining birds and the age of first breeding does not change, any excess mortality during a single winter might affect breeding numbers in three ways: immediately, by the loss of adults from the breeding population; annually for four years, by the loss of immature birds in second to fifth winters; and after four years by the loss of first year birds now entering the breeding population for the first time.

When some allowance has been made for the variation in ringing effort, it seems likely that the guillemots from eastern areas have suffered worst. The Orkney and

Winter mortality, December to February, for 1980-81 compared with 1967-79 for British and Irish ringed guillemots and razorbills

	Guillemot (Iria aalge)	Razorbill (A	lca torda)
Ringed birds at risk+	1980–81	1967-79	1980-81	1967-79
	18,000	83,000	15,500	122,500
Recoveries reported: Oiled 'Found dead'++ Total	61	68	20	55
	20	56	4	84
	81	124	24	139
Recoveries/1,000 at risk: Oiled 'Found dead' Total	1.1	* 0.8 0.7 * 1.5	1.3 * 0.3 1.5	0.4 0.7 1.1

* indicates significantly higher rate than for the other period with probability < 0.001

+The figure for birds at risk has been calculated from the ringing totals reported over the last 25 years (1980 figures provisional) with allowance made for first year mortality (50 per cent), annual immature mortality of 16 per cent and adult mortalities of 6 per cent for guillemot and 9 per cent for razorbill⁴⁻⁷.

++'Found dead' recoveries include only beached birds not reported as oiled. Birds known to have been shot, snared or caught during fishing operations have been excluded throughout.

Shetland guillemot populations will be reduced by 2 per cent immediately, followed by 1 per cent per annum for three more years and a further 4-5 per cent in 1985 when the 1980 cohort should start to breed. It is possible that the guillemots from Grampian colonies may have suffered as badly. However, the adults and immatures from north-west Scottish colonies seem to have survived better but the increased mortality of first year birds will affect breeding numbers in four years. In this area 5 per cent of the breeding razorbills may have been lost. Saltee results indicate that neither species suffered particularly high mortality last winter.

Even the largest predicted annual

decreases in populations (about 5 per cent) are probably too small to be detected by current census techniques8. Recent breeding population studies indicate that population changes on this scale (or slightly greater) have affected many auk colonies in Britain and Ireland over the last decade^{7,9}. However, this oiling mortality, if repeated over several winters, would result in a steady decline of guillemot and razorbill populations over much of northern Britain. Together with the threat of summer pollution at colonies posed by inshore oil exploitation, all those responsible for the conservation of seabirds, particularly in Scotland, have a very real cause for concern.

Moonquake meanings

from Peter J. Smith

As the Earth has earthquakes, so the Moon has moonquakes; and insofar as events of both types have definite foci, generate seismic waves and radiate energy, they are clearly recognizable as belonging to the same class of phenomena. Thereafter the resemblance weakens, for the distributions of lunar and terrestrial shocks in both space and time are quite different. Whereas most earthquake epicentres lie along narrow bands coincident with major crustal features, moonquake epicentres exhibit no such correlation. Whereas earthquake foci lie at depths of 0-700 km, their counterparts in the Moon mostly occur in the depth range 700-1,100 km (deep moonquakes), although there are also a few at less well determined depths of rather less than 200 km (shallow moonquakes). And whereas earthquakes taken together demonstrate no clear temporal patterns,

Peter J. Smith is in the Department of Earth Sciences, Open University, UK.

deep moonquakes have a strong periodicity of 27 days. Lunar quakes also differ from the terrestrial variety in that they occur repeatedly at a limited number of foci.

The reason for all these differences is evidently the influence of different tectonic styles, the importance of which is reemphasized by new calculations of lunar seismic energy and moonquake source parameters carried out by Goins et al. (J. geophys. Res. 86; 378, 1981). This is not the first time that an attempt has been made to determine the seismic energy released by moonquakes, although Goins and his colleagues claim, certainly correctly, that previous estimates were unsatisfactory in that they failed to take sufficient account of such factors as instrument frequency response and the effects of intense scattering near the lunar surface. On the other hand, it is not entirely clear that many of the conclusions drawn by Goins et al. could not equally have been drawn from the earlier calculations, notwithstanding that they apparently underestimated seismic energy by a factor of about 100 and moonquake magnitudes by a factor of about 2. But that is no argument against having the correct, or at least more 'realistic', figures at last; and in any case Goins and his co-workers have also made the first determinations of additional source parameters such as seismic moment and stress drop.

According to the new figures, then, the 500 or so deep moonquakes with body wave magnitudes (m_b) greater than 1.6 (maximum $m_b = 3.0$) recorded annually by the Apollo Passive Seismic Net release energy of 8×10^{13} ergs a year. So where does this energy come from? Or to put it another way, what is the basic mechanism for the generation of deep moonquakes? Comparison with the Earth is no help here, for deep moonquakes have no terrestrial equivalents. What is relevant, however, is the fact that the marked periodicity of 27 days in the event occurrence frequency at each deep moonquake focus exactly matches the dominant 27-day period of the

tide induced in the Moon by the Earth. Moreover, the number and size of deep moonquakes in any given month also correlates with the 206-day variation in the lunar tide resulting from the perturbation of the Moon's orbit by the Sun. The occurrence times of deep moonquakes are thus evidently controlled by tidal forces; and since the tidal energy dissipated in the Moon is $10^{21}-10^{22}$ ergs a year, this source is obviously more than sufficient.

But the tidal energy dissipated in the Earth is, at 10²⁷ ergs a year, even greater than that dissipated in the Moon. Why, then, are there apparently no tidally induced earthquakes? For this interesting conundrum Goins and his colleagues offer three explanations, not necessarily mutually exclusive. One is that terrestrial lithospheric stresses due to lunar forces are about an order of magnitude smaller than the lunar stresses due to Earth forces at moonquake depths. The second is that there may indeed be some tidal earthquakes but that most, if not all, of them are masked by tectonic earthquakes and microseismal noise. And third, the 'dynamic character of the Earth's interior' generally precludes the development of long-term strain buildup at terrestrial depths of greater than about 700 km.

The latter two explanations thus bring us directly to tectonic style, which seems to be much more important than the relative magnitudes of possible driving forces when it comes to a planet's seismic characteristics. For example, the thermal energy available in the Moon $(2 \times 10^{26} \text{ ergs a})$ year) is not much less than that in the Earth $(9 \times 10^{27} \text{ ergs a year})$, but the different sizes of the two bodies lead to different distributions of temperature with depth and hence to different tectonic regimes. The result for the Earth is a thin lithosphere, lithospheric breakup, plate motion and a dominant near-surface seismic distribution generated tectonically. On the Moon, by contrast, the lithosphere is much too thick to fracture; and the temperature-depth distribution, and hence the shear modulus-depth variation, is such as to concentrate the tidal stress into a particular depth range. Thus whereas heat is the chief fundamental influence on terrestrial seismicity, the corresponding lunar influence is tidal.

Not that things can be quite as simple as that. Although tidal stresses vary smoothly over the lunar surface, moonquake epicentres do not. Most of them lie on the Moon's nearside, although that could merely reflect the difficulty of detecting farside events with nearside seismometers. But of greater significance, perhaps, is the highly uneven distribution of epicentres on the nearside, and in particular, a marked disinclination of epicentres to lie in the south-east quadrant of the face. This could be simply a matter of chance; but it might also suggest that, notwithstanding the dominance of tidal forces, the precise locations of foci within the 700-1,100 km

layer are governed by pre-existing inhomogeneities or zones of weakness.

Then there are those shallow moonquakes, hitherto mentioned but otherwise ignored. Although the passive seismic net has only been recording about five of these a year with m_b greater than 2.2, their maximum magnitude (4.8) is much greater than that of deep moonquakes (3.0) and the total seismic energy released by them annually is 2,500 times greater (2×10^{17} ergs a year). Yet they demonstrate no obvious periodicities in their times of occurrence, are not related to any obvious surface features, and do not occur repeatedly at the same foci. Moreover, although they release far less energy than even intraplate earthquakes (about 3 per cent of terrestrial seismic activity), their stress drops are comparable with, and sometimes even higher than, those of most terrestrial events.

Europe regains the lead in atomic physics?

from M.R.C. McDowell

THE First European Conference* on Atomic Physics (including Molecular Physics) shattered the belief that the United States necessarily leads the world in any branch of physics. This resurgence in Europe is not confined to a few countries—important new advances were reported from Poland and Spain, for example.

The charge exchange reaction

 $(X^{q+} + e) + Y^{p+} \rightarrow X^{q+} + (Y^{p+} + e)$ in which an electron is transferred from one ion (or atom) to another, is attracting much theoretical and experimental interest. One reason is that it is now clear that charge exchange-assisted recombination can move the ionization equilibrium in thermonuclear plasmas several stages of ionization away from the 'coronal equilibrium' values. At impact velocities Vgreater than the orbital velocity of the captured electron, energy and momentum are transferred with the electron, and the corresponding momentum transfer factors in the expression for the cross-section can greatly reduce the rate of the process. The process leads to highly specific final states.

A. Macias and A. Riera (Universidad Autonoma de Madrid) have clarified this momentum transfer problem by showing that the translation factors introduce a new class of coupling which may be more important than dynamical coupling in determining the final state. Further advances in our understanding of charge exchange came from J. H. McGuire (Hans-Meitner Institute, Berlin) who, with his student P. R. Simony (Kansas State University), has shown that the v^{-11} dependence of the proton-hydrogen charge exchange cross-section is manifested in a secondary maximum in the differential cross-section, and this was confirmed in a different theoretical

states with maximal overlap with the initial state. It became clear in discussion that no one knows the exact velocity dependence, at high velocity, of any charge exchange process.

Theoretical advances also dominated the discussion on the behaviour of atoms in very intense electromagnetic fields, the latter being of great interest in the astrophysics of White Dwarfs and Neutron Stars, as well as in the ablation of inertial fusion targets. Fields of interest range up to 10^{13} G, although currently available laboratory fields are restricted to about 4×10^{5} G. P. Cavaliere, C. Leone and R. Zangara (University of Palermo, Italy) have shown that the normal double-loop

Zangara (University of Palermo, Italy) have shown that the normal double-loop pattern observed in electron impact triple differential ionization measurements splits into a quadrupole pattern when a laser beam, at right angles to the electron beam, also interacts with the target. In the field-free case the transition is $s \rightarrow p$, but with the field on, it may be $s \rightarrow s$ or $s \rightarrow d$, the electron emitting or absorbing one photon. The quadrupole pattern appears to be associated with absorptions $[s \rightarrow (p+1)]$. They also show that the process of laser-assisted electron impact ionization of atoms can lead to appreciable laser gain. F.

M.R.C. McDowell is Professor of Applied Mathematics at Royal Holloway College, University of London, and was assisted by both D.N. Stacey, Clarendon Laboratory, Oxford and G.V. Marr, University of Reading in preparing this report.

^{*}The Conference, sponsored by the Atomic Physics Division of the European Physical Society, was held at the University of Heidelberg (April 6-10 1981), and was organized by Professor G. zu Putlitz. The two-volume Book of Abstracts (eds. J. Kowalski, G'zu Putlitz, H. G. Weber) is published in Europhysics Conference Abstracts.

M. Faisal (University of Bielefeld, Germany) with A. Larni and N. K. Rahman (University of Pisa) have demonstrated theoretically that laser gain should also be exhibited in laser-assisted recombination. Detailed calculations for recombination to He (51P) suggest that high gain can be obtained at low laser intensity if the electrons are highly monochromatic. Photoionization of atomic hydrogen in intense magnetic fields has been calculated by S. M. Kara (British Nuclear Fuels), who finds intense resonances at the Coulomb-modified Landau levels. An exact scaling theorem for the isoelectronic sequence has subsequently been given by G. Wunner, H. Ruder, W. Schmitt, H. Herold (University of Erlangen, Germany) and M. McDowell (Royal Holloway College, London University), which reduces to a simple scaling in the dipole approximation. This should be experimentally testable, using a synchrotron as a light source.

For field-free photoionization, U. Heinzmann (University of Munster, Germany) followed up his earlier work on production of spin-polarized photoelectrons by reporting absolute measurements of the eigen-quantum defects in Ar, Xe and Kr from threshold to 40 eV, which join on smoothly through threshold with the bound-bound transition values of n³ times the oscillator strengths f_{nn} from level n to level n'. This is very direct experimental evidence for the validity of Seaton's multichannel quantum defect theory, which is of considerable astrophysical importance. (For Xe, see U. Heinzmann Appl. Opt. 19; 4087, 1980.)

Dramatic developments were reported in the study of nuclei by optical spectroscopy. Two experimental advances, the tuneable laser and on-line mass separation, have allowed the charge radii, spins and moments of long sequences of radioactive nuclei to be measured. In particular, the variations in charge radius (giving rise to so-called 'isotope shifts' in atomic spectral lines) have given a great deal of nuclear structure information over the years, but until quite recently very little work had been done on light elements or unstable nuclei. Suddenly, vast quantities of data are appearing, largely due to the efforts of two groups (based at Mainz and Orsay) working at the ISOLDE mass separator at CERN. Rubidium, for example, has two naturally occurring isotopes; results for over 20 isotopes are now available, including several isomers. They show, remarkably, that the nuclear size actually decreases as the neutron number rises from 40 to the shell closure at 50; there is then a sharp increase, much more rapid than is predicted by the usual nuclear models.

Other elements show equally interesting features, the most striking so far being the shape isomerism found in neutron-deficient mercury isotopes.

The results are a valuable testing ground for nuclear theory. The variations in

nuclear size show broad overall features which should lead to a better insight into the systematics of nuclear behaviour, while the finer details, for example isomer shifts, depend sensitively on the structure of the individual nuclei concerned.

The work of V. S. Letokhov (Academy of Sciences, Moscow) on the resonance interaction of laser radiation with single atoms now allows the simultaneous availability of high spectral resolution with the ultimate in sensitivity and detection selectivity in that he claims to be able to detect and do physics on one atom in 1012. High Rydberg atomic states have now been demonstrated to be very attractive for high-resolution spectroscopy and metrological work (H. Walther, Munich). Exciting a single Rydberg state by laser opens the possibility of higher-resolution measurements of the fundamental constants. Beam foil spectroscopy continues to be used and recently has allowed the observation of radiative transitions between bound states of the negative ion of lithium (I. Martinson, Lund).

The study of molecular systems is entering a new and exciting phase. New avenues of experimental study are being opened up by the multichannel quantum defect theory (M. J. Seaton, London; Ch. Jungen, Orsay), typified by work reported by S. Krummacher (Freiburg) using the Orsay synchrotron light source to study the inner shell photoionization of CO. It is important to note that Heinzmann's direct verification of this theory allows absolute calibration. High-resolution spectroscopy of Ch reported by J. Le Calvé (Saclay), threshold electron spectroscopy (M. Kurepa, Belgrade) and resonance fluorescence (T. Möller, Hamburg) on the same molecule show that there is much which can be obtained by application of both new and traditional techniques to the analysis of individual molecular systems.

A gradient of membrane protein in the retina

from Colin J. Barnstable

THE MECHANISM by which cells sense and signal their position within an organ or organism remains one of the least understood problems in biology. Many experimental systems such as chick limb development, hydra regeneration and insect cuticle formation have indicated that gradients of positional information exist and can be sensed and acted upon by the relevant cells. Both the nature of these gradients and the sensing mechanisms are unknown. In the nervous system, the position of an individual neurone has important consequences for the nature of its synaptic input and the target it innervates. For example, motor neurones in the developing spinal cord migrate to particular positions and the resulting clusters of cells can be shown to be committed to innervate a particular muscle1. Innervation is only achieved after the growing axons reach this correct target some distance away. In this system the mechanism that specifies which motor neurones will innervate which muscles, and the mechanisms by which the growing axon reaches its target, remain unknown.

This general problem of neural specificity has also been intensively studied in the visual system and particularly in the topographical projection of retinal ganglion cell axons to the optic tectum. One current debate centres around the mechanism by which this ordered

Colin J. Barnstable is Instructor in Neurobiology, Harvard Medical School. projection is formed. In some fishes it may be the result of a maintained topography in the optic nerve². In the adult cat³, on the other hand, the ganglion cell axons are mixed up in the optic nerve and sort out at their targets. This implies that some form of 'chemoaffinity' between axon and target cell exists. Models for this have varied from a strict 'lock-and-key' relationship between each ganglion cell axon and its tectal target neurone to a quantitative gradient or gradients of interaction molecules arranged according to particular retinal axes⁴.

These interaction molecules have usually been studied in terms of selective cell adhesion using methods developed for studying the aggregation and sorting of a variety of embryonic tissues (see ref. 5 for a review). In the retino-tectal system it has been shown that in general cells from a given portion of retina preferentially adhere to cells from the tectal area that includes their normal synaptic target. From studies such as these it has been concluded that there are several interacting gradients that can be used to specify cell position and subsequent interaction. None of these studies, however, has successfully identified the molecular nature of these gradients.

A recent paper by Trisler, Schneider and Nirenberg⁶ has demonstrated that a gradient of concentration of a particular molecule does exist across the avian retina. To demonstrate this Trisler et al. looked

for, and found, a monoclonal antibody that bound more strongly to dorsal retina than ventral retina. When 14-day chick embryo retinas were cut into eight segments along a dorsal-ventral axis and assayed for antibody binding, the most dorsal segment bound 35-fold more antibody than the most ventral. Presumably the extremes of the gradient show a much greater difference. The antigen detected by the monoclonal antibody has been named TOP, after 'toponymic' which the authors define as 'a marker of position'. It appears to be a cell surface protein since it can be assayed on living cells, is heat labile and is trypsin sensitive. Immunocytochemical localization of antigen in 14-day chick embryo retina showed that it was present in all layers and, therefore, possibly in all cell types. The gradient is thought to represent differences in the amount of antigen per cell rather than regional differences in cell or membrane concentration since mechanically dissociated cells gave different intensities of immunofluorescence according to the part of the retina chosen. Essentially all the features of the gradient were found at every age tested from 4-day old embryo to adult.

Whatever the mechanism for generating the gradient, simple 'organizing' or 'controlling' areas outside the retina seem not to be involved. The evidence for this comes from an unusual embryo found by Trisler et al. that had a third eye in the middle of the forehead facing in a dorsoanterior direction. Even though the eye was in an abnormal orientation, the gradient of TOP antigen showed a normal orientation with respect to its own dorsalventral axis defined by the choroid fissure.

The importance of this paper for biology in general is that it has demonstrated a molecular gradient in a particular organ. Its importance in aiding our understanding of neural specificity will depend upon whether the cells within the retina or in the optic tectum use the information contained in the gradient for their physiological interactions.

Galactic nuclei

from R.A.E. Fosbury

SINCE the upsurge of interest in Seyfert galaxies and the discovery of quasars in the early 1960s, galactic nuclei have been prime targets for the application of new observational techniques. The more active galactic nuclei have not disappointed observers as their high luminosity extends over the whole electromagnetic spectrum. The current status of research on galactic nuclei, both active and 'normal', was examined by the participants at a recent conference* at the Royal Greenwich Observatory.

In the spiral Seyfert galaxies, the nucleus has a profound influence over the physical conditions in a region of typical diameter one kiloparsec $(3 \times 10^{21} \, \text{cm})$. The optical observers call this the narrow line region (NLR) since it is the source of the strong forbidden emission lines with widths of order 300 km s-1 characteristic of this class of object. The region is also now recognised to be a source of radio radiation with a relatively steep spectrum. Andrew Wilson (University of Maryland) reviewed new radio observations, primarily from the Very Large Array (VLA) in New Mexico, which showed the Seyferts to be intermediate between normal and radio

galaxies. Indeed, some show a double or triple structure on a scale of a few arc seconds, reminiscent of a classical double radio source but prevented from bursting out of the immediate nuclear environment by a spiral of dense interstellar medium. Wilson noted an interesting lack of correlation between radio and optical axes in the Seyferts which may suggest that the nucleus is not influenced very much by what the rest of the galaxy is doing. Spencer, Booler, Steward and Lonsdale (Jodrell Bank) complemented the VLA work by showing similarly high-resolution radio maps made at lower frequencies with the new multi-telescope radio-linked interferometer which spans a significant fraction of the western side of Britain. Because of the steep spectra, this instrument is particularly suited to studies of the nuclear surroundings. The small angular size subtended by the nuclei makes it difficult to reconstruct the geometric and kinematic state of the various components. It has long been realised that the emission line profiles are a rich source of such information, although difficult to interpret. Mark Whittle (Institute of Astronomy, Cambridge) reported an extensive study of the profiles originating in the NLR and at last offered some hope of being able to distinguish

between inflowing and outflowing material from careful comparisons of the asymmetries seen in lines from different ionization states. Although it is generally agreed that most of the emission line radiation emitted by active nuclei is the result of photoionization processes, there is still considerable uncertainty whether the origin of the ionizing continuum is nonthermal with a power-law spectrum or a combination of this with thermal radiation. Shock processes have been advocated for some nuclei which do not show a strong continuum. Even for these. Daniel Péquignot (University of Meudon) illustrated the versatility of photoionization models to explain some of the lowionization spectra. His models produce the strong auroral line with regions of high density and reproduce the optical spectra quite satisfactorily using a two-component ionizing spectrum; the approach was, however, running into some difficulties with the UV emission line observations.

Bernard Pagel (Royal Observatory, Herstmonceux) considered the elemental abundances of both normal and active nuclei. With the caveat that the abundance determination methods used for nuclei are somewhat unreliable, it is perhaps surprising that activity seems to have little effect on chemical composition. In fact, all the observed galactic nuclei seem to have very similar abundances and, in particular, there is no evidence for secondary processing in nuclear HII regions as the nitrogen to oxygen ratio is consistent with that of oxygen to hydrogen. How normal are 'normal' galactic nuclei anyway? Robert Sanders (University of Groningen) sketched a picture of recurrent activity in which gas clouds within the inner few hundred parsecs lost a small fraction of their mass to a black hole on each collision and produced one event of about 1056 ergs every 107 years. He supported the thesis with reference to our own Galaxy by pointing out the expanding ring seen in molecular emission lines which should oscillate with about that period. New X-ray observations of our own nucleus were presented by Brin Cooke (University of Leicester). The orbiting Einstein Observatory has shown a number of hardspectrum point sources together with a diffuse component extended along the galactic plane. One of the (non-variable) point sources is coincident with the radio source Sagittarius A west and he pointed out that the radio/X-ray flux ratio is about the same as that in the radio galaxy Centaurus A. Willem Wamsteker (VILSPA) described some optical observations of the nucleus of the nearby spiral galaxy M83 which showed noncircular motions very similar to those seen in our Galaxy.

The second half of the conference collected together important observations

Lucifer dyes—highly fluorescent dyes for biological tracing

Walter W. Stewart

National Institute of Arthritis, Metabolism, and Digestive Diseases, National Institutes of Health, Bethesda, Maryland 20205, USA

Lucifer dyes are intensely fluorescent 4-aminonaphthalimides which are readily visible in living cells at concentrations and levels of illumination at which they are nontoxic. Because of their low molecular weight they frequently pass from one cell to another; this widespread phenomenon, termed dye-coupling, is thought to reveal functional relationships between cells. Lucifer dyes can also be used for ultrastructural tracing by comparison of electron micrographs with light micrographs of the same thin section. In addition, they show promise for backfilling neurones through cut nerves, for visualizing the results of retrograde axonal transport and for the covalent labelling of macromolecules.

SINCE their introduction in 1978 Lucifer yellow CH and Lucifer yellow VS have been used with considerable success as intracellular markers in a wide variety of biological systems. Both dyes contain the same sulphonated 4-aminonaphthalimide moiety, but they differ in the substituent on the imide nitrogen (Fig. 1). Their syntheses, to be reported elsewhere, are based on the commercial wool dye brilliant sulphoflavine (CI 56205). The dyes have similar spectral properties: absorption maxima at 280 nm and 430 nm, corrected emission maxima near 540 nm, and quantum yields of about 0.25. The high quantum yields make possible the detection of the dyes at low concentration, and the wide separation between the absorption and emission maxima facilitates excitation at one wavelength and observation of fluorescence at another.

The dyes differ in their chemical properties, but both can be bound to tissue. Lucifer yellow VS is a vinyl sulphone that reacts rapidly with amino and sulphydryl groups but is extremely stable in water; even in weak base (pH 9.0) its half life is about one week at room temperature. The dye combines rapidly and covalently with proteins and presumably with other tissue constituents containing sulphydryl or amino groups. Lucifer yellow CH, on the other hand, has a free hydrazido group and reacts with aliphatic aldehydes at room temperature. Aldehydecontaining fixatives bind the CH dye to tissue, presumably through the hydrazido group. Aqueous solutions of this dye appear to be chemically stable for at least several months at room temperature.

So far the CH dye has been used more often than the VS dye, perhaps because the latter is not yet commercially available;

Fig. 1 Structural formula of Lucifer dyes. Both dyes are 3,6-disulphonated 4-aminonaphthalimides. For the lithium salt of Lucifer yellow CH (often referred to simply as Lucifer yellow CH), R is -NH-CO-NH-NH₂; for the lithium salt of Lucifer yellow VS, R is m-phenyl-SO₂-CH=CH₂. About ×24,000,000.

which one is best suited to a particular application can only be determined empirically.

The most frequent application of Lucifer yellow CH has been to reveal the shape of individual neurones 1-5. It has been used to determine the branching pattern and course of regenerating neurones 6-7. Because of the low toxicity of the dye, direct in vivo observations on the regeneration of dye-filled neurones may be possible. Lucifer yellow CH has been used in the study of developing systems: in the development of molluscs 8, for example, and in the exciting work by Goodman and Spitzer on the development of the grasshopper nervous system 9. I describe here other applications of these fluorescent tracers in the hope that their many potential uses can be rap-dly exploited.

Dye-coupling revealed by intracellular injection of Lucifer yellow

Neurones and other cells can be marked with Lucifer yellow CH by injecting the dye through a micropipette using pressure or iontophoresis. The dye spreads quickly throughout the body and processes of the injected cell, but does not cross the cell membrane¹. The low molecular weight (457.2) and intense fluorescence of the dye offer several advantages over other tracers. (1) A cell can be stained in its entirety with a relatively small amount of dye. Illumination sufficient for photomicrography of live cells does not noticeably alter their physiology. (2) In preparations which are sufficiently transparent one can determine whether the distribution of dye found after fixation is the same as that seen in the living state. (3) Most importantly, the dye frequently spreads in vivo from the injected cell to certain nearby cells. This movement of dye from cell to cell has been termed dye-coupling¹. In certain cases, dye-coupled cells are known to be electrically coupled to each other. Two examples are horizontal cells in the turtle retinal and the septate axon of the crayfish (K. Futamachi and W.S., unpublished). In the embryo of the mollusc Patella, however, dye-coupling between macromeres was detected without knowing whether the cells were electrically coupled and was used to study the development of the embryo⁸. Presumably in many (but not necessarily all) instances dye-coupling and electrical coupling have a common basis. In any case, dye-coupling offers a method of recognizing certain functional connections between cells by morphological means.

A pair of neurones called Leydig cells occurs in each segmental ganglion of the leech *Hirudo medicinalis*. These cells are known to be electrically coupled³⁰, and Fig. 2 shows that they are dye-coupled as well. Two neurones in the ganglion contain dye: the Leydig cell that was injected and the contralateral Leydig cell into which dye spread. The transfer of dye presumably occurred at the sites of contact between the arborizations of the two neurones. Unexpectedly, dye also spread from the injected neurone to processes in the ipsilateral axon bundles

Fig. 2 Leech ganglion containing a Leydig cell injected intracellularly with the lithium salt of Lucifer yellow CH. a, The lower cell was pressure-injected with a 5% solution of dye. The tissue was allowed to stand for 90 min at room temperature and was then fixed at 4 °C for 12 h in 4% formaldehyde in 0.15 M sodium phosphate buffer, pH 7.4. The ganglion was embedded in glycol methacrylate as previously described 1 . The fainter cell body (top) is the contralateral Leydig cell, which is dye-coupled to the injected cell. $\times 107$. b, Detail from a. The ipsilateral nerve contains two fluorescent processes—one from the injected neurone, the other from a dye-coupled neurone in the adjacent ganglion (see text). $\times 180$.

leaving the ganglion (Fig. 2b). These are probably axons from Leydig cells in adjacent ganglia, as Kent Keyser has independently demonstrated in greater detail (personal communication). As both adjacent ganglia had been removed before injection, the sites of coupling to the two dye-coupled processes must have been in the remaining ganglion or in the short lengths of attached nerve. Here and in similar situations Lucifer yellow CH is useful for gross localization of the sites of intercellular communication.

The sensitivity of Lucifer yellow CH was compared semiquantitatively with that of two other tracers, Procion yellow and horseradish peroxidase. Horseradish peroxidase is often used for intracellular staining^{18,19} and is detectable by both light and electron microscopy. When 5% solutions of Lucifer yellow CH and horseradish peroxidase were injected by pressure into leech neurones, the two tracers appeared roughly equal in their ability to reveal morphological detail as judged visually with the light microscope (W.S. and K. Muller, unpublished). Horseradish peroxidase, however, cannot be seen in living tissue and is thought not to pass between dye-coupled cells²⁰. Procion yellow, a fluorescent tracer previously used for intracellular injection²¹, has about 1% of the fluorescence intensity of Lucifer yellow and in comparably marked cells reveals much less morphological detail¹.

Backfilling with Lucifer yellow CH

Neurones can also be filled with dye through their processes rather than by injection of dye into their somata. Backfilling, introduced by Iles and Mulloney²², is carried out by simply immersing the cut end of a nerve in a pool of tracer. The tracer moves up the axons of the nerve, either by diffusion or in response to an externally applied electric field, and fills the cell bodies of the neurones with processes in that nerve. This technique has been used with Procion yellow²², with cobalt chloride^{23,24}, and with horseradish peroxidase²⁵. Lucifer yellow CH is at least as suitable for backfilling as these tracers. Moreover, since neither the dye nor the process of backfilling appears to alter physiological properties noticeably, and since the dye can usually be seen *in vivo*, one can first identify a backfilled cell by its fluorescence, then impale it with a micropipette and investigate its electrophysiology.

Figure 3a is a fluorescence photomicrograph of the buccal ganglia of the freshwater planorbid snail Biomphalaria glabrata. The preparation was backfilled with the lithium salt of Lucifer yellow CH through the nerve innervating the left salivary gland. The two largest cells containing dye can usually be identified by other criteria such as size, position, and branching pattern. These cells appear to be salivary effector neurones and may be homologous to the cells described by Kater in Helisoma26 and Benjamin in Lymnaea²⁷. The fluorescent cells were impaled after they had been backfilled, and their physiology appeared normal. In particular, action potentials in the left cell produced one-for-one depolarizing potentials in the salivary cells (Fig. 3b, c), and depolarizing and hyperpolarizing current passed from either cell to the other, suggesting that they were electrically coupled (Fig. 3d, e). These results are similar to those obtained from preparations which had not been backfilled. After fluorescence photomicrography of the ganglia (Fig. 3a), the physiology of both cells was still normal, and they remained electrically coupled (Fig. 3f, g). In this system, therefore, the amount of light needed for fluorescence photomicrography is much less than that which causes photosensitized damage or killing of cells that contain dye. In the method of cell killing devised by Miller and Selverston, the illumination level which killed Lucifer-filled cells in 5 min was 1,000 times the level required for visualization of processes in the neuropil²⁸.

Lucifer dyes as tracers in electron microscopy

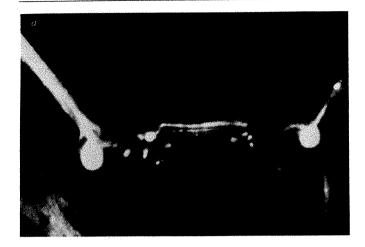

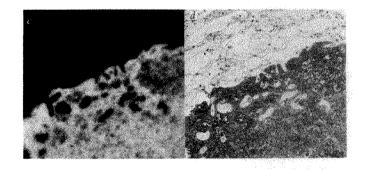

Since the Lucifer dyes described here do not contain a heavy atom, they have no useful electron density. Their intense 

Fig. 3 Live neurones stained by backfilling with the lithium salt of Lucifer yellow CH, and electrical responses recorded after staining. The cut end of the left salivary nerve of a snail (B. glabrata) was drawn into a small drop of a 3% solution of dye on a square of polyethylene about 1 mm on each side. For 1 h a potential was imposed so that a positive, constant current of 30 nA flowed from the bath to the drop of dye. The buccal ganglia were rinsed in a Ringer's solution, and the stained cells were identified with fluorescence optics. The large dye-filled cell in the left buccal ganglion was impaled with a microelectrode (b and c, lower trace). A salivary cell was impaled with a second electrode (b and c, upper trace). The microelectrode was then withdrawn from the salivary cell and used to impale the large cell on the lateral margin of the right buccal ganglion (d and e, records for the right cell are on top). The current traces show when current (about 0.25 nA) was injected, using an active bridge circuit (not accurately balanced in all records), first into one cell and then the other. The live prepartion, a, was then photographed using epifluorescence with a Zeiss Ultraphot. The conditions of photography were: 6.3X Neofluar lens (0.20 numerical aperture), HBO 200 W mercury arc lamp, heat filter and BG-12 excitation filter, FL-500 dichroic splitter, 500 nm barrier filter, 30 s exposure. ×66. After photography, both lateral cells were impaled again, producing the records shown in f and g. Vertical calibration indicates 50 mV for all records; horizontal calibration indicates 1s for c and 2s for all other records.

fluorescence, however, allows them to be used as tracers for electron microscopy by an indirect procedure. An ultrathin section mounted on a grid is examined with a fluorescence microscope to identify cells or processes that contain dye, and then the same section is examined with the electron microscope. Figure 4 shows light and electron micrographs of the same areas of a neurone in the right parietal ganglion of the snail B. glabrata; this neurone can often be identified by its size and position. To make this type of comparison, tissue is conventionally processed for electron microscopy except that osmication is omitted, since even brief exposure to osmium tetroxide greatly reduces Lucifer fluorescence.

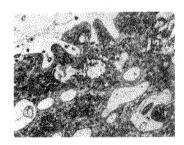

Fig. 4 A cell in the right parietal ganglion of the freshwater snail Biomphalaria glabrata was injected with Lucifer yellow CH, fixed for 4 h at 23 °C in a pH 7.4 12.5 mM Na°/H° HEPES buffer containing 2% glutaraldehyde, 1% formaidehyde, and 25 mosM balanced salts, dehydrated in graded alcohols, and transferred to anhydrous acetone at 4 °C. The ganglion was stained for 1 h at 4 °C in 1% hafnium tetrachloride in acetone, then rinsed in acetone and embedded in Spurr's resin 42. (The fixative and rinse solutions also contained 1% HfCl₄ in this experiment, but not in most.) a, Silver section on a hexagonal grid (Polaron) was illuminated through a Zeiss 63X OD lens (0.90 numerical apertume) with an Osram 50 W HBO lamp and photographed with a 15 s exposure on Ektachrome 400 film pushed to ASA 800. ×640. b, The same section shown in a, photographed with the electron microscope after uranium and lead staining. ×640. c, Detail from a. ×1,500. d and e, Detail from b. ×1,500 and ×3,700. Photographed at 80 kV.

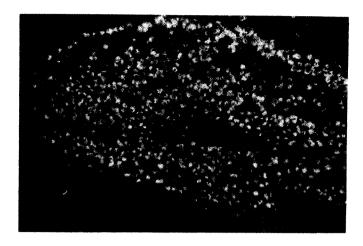

Fig. 5 Isthmo-optic nucleus of chick labelled by retrograde axonal transport of Lucifer yellow VS. The vitreous humour of the contralateral eye was injected with 25 μl of 5% Lucifer yellow VS; the injection damaged a portion of the retina. After 21 h the chick was anaesthetized and fixed by perfusion with buffered 4% formaldehyde. The other eye was not injected, and its contralateral isthmo-optic nucleus showed almost no fluorescence. $\times 200$.

Post-fixation staining can be omitted entirely, but tissue processed in this way generally lacks sufficient contrast and electron density to give useful images. Adequate contrast is generated by staining tissue en bloc in 1% hafnium tetrachloride in anhydrous acetone at 4 °C, a procedure introduced by Morris Karnovsky (personal communication). The tissue is then rinsed in acetone and embedded in Spurr's resin. When a thin section (grey or silver) on an ordinary electron microscope grid is illuminated using epifluorescence with an intense arc lamp, the fluorescence of the marked cell is bright enough to be photographed on a fast colour film with a 15-s exposure. The same thin section is then conventionally stained with uranium and lead; the areas that had been found fluorescent are located and photographed with the electron microscope. Surprisingly small areas can be identified with confidence when the light and electron micrographs are compared. In Fig. 4c, d, for example, there are dye-free areas only 500 nm in diameter that are easily recognized in both the light and electron micrographs. The areas from which dye is excluded lie within the perimeter of the cytoplasm of the injected cell and may be penetrating processes of other cells²⁹ Dye-filled processes 500 nm in diameter can usually be found with ease, while 200 nm processes are locatable with greater difficulty.

The necessity of avoiding osmication to preserve fluorescence entails some disadvantages. Membranes either cannot be seen or, more often, appear as thin grey lines (Fig. 4e) instead of the dark black bilayer commonly seen with conventional fixation. The poor visualization of membranes makes the method described here unsuitable for some applications. For example, synapses in the leech central nervous system are difficult to recognize because membranes and associated synaptic specializations lack the contrast they normally have with osmium post-fixation (K. Muller, personal communication).

Since Lucifer yellow CH has no significant electron density of its own, it was possible to test whether either the dye or the process of injection had an effect on the ultrastructure of an injected neurone. The paired Retzius cells of the leech³⁰ were convenient test objects. In each of three segmental ganglia, one Retzius cell was injected with dye and one was not. The tissue was immersed in a cacodylate-buffered fixative²⁰, then processed as described in the legend to Fig. 4. When thin sections

were examined with the electron microscope, both cells were recognizable by their size and position. (The injected cell had previously been identified by its fluorescence.) The ultrastructural morphology of the two cells was virtually the same, suggesting that neither the dye nor the process of injection had caused significant morphological changes (K. Keyser and W.S., unpublished). This experiment illustrates an advantage of an ultrastructural tracer that does not rely on electron density for its detection: the appearance of the marked tissue is not necessarily changed.

Retrograde axonal transport

A useful technique for studies of vertebrate neuroanatomy relies on the phenomenon of retrograde axonal transport, which causes certain exogenous proteins to be carried from axon terminals to the cell body³¹. Kristensson, Olsson, and Sjöstrand

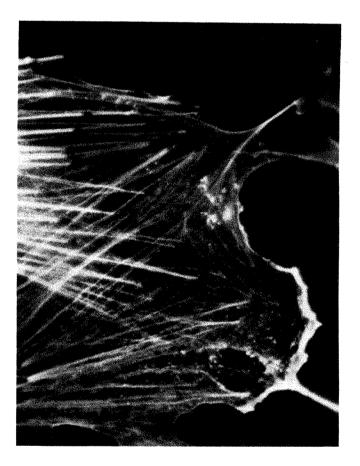

Fig. 6 Indirect immunofluorescence staining of actin filaments with Lucifer-labelled antibodies. Cultured human lung cells, W138, were fixed and treated with rabbit anti-actin antibody, then with Lucifer-labelled goat IgG anti-(rabbit IgG); the procedures were those described by Lazarides⁴³. The Lucifer-labelled antibody was prepared as follows. To 50 mg of Miles-Yeda goat IgG anti-(rabbit IgG) dissolved in 1.8 ml 0.5 M pH 9.0 carbonate buffer was added 0.52 mg Lucifer yellow VS in 1.0 ml carbonate buffer. These weights correspond to a nominal 3 mol of Lucifer per mol of protein, but since Lucifer yellow VS is hygroscopic, less dye was actually present. The mixture was allowed to stand for 3 h at room temperature, then unreacted dye was removed by chromatography with phosphate-buffered saline on Sephadex G-25. The optical densities at 280 nm and 430 nm indicated a dye to protein molar labelling ratio of approximately 2.3. About ×500.

in changes conformational monitoring pH-induced macromolecules.

showed in 1971 that horseradish peroxidase appeared in the cell bodies of neurones near whose terminals a solution of horseradish peroxidase had been introduced³². This marker has since been used both to trace pathways in the central nervous system and to study the mechanism of transport itself. The LaVails and others have shown that peroxidase moves within axons at a rate of about 100 mm per day (ref. 33). Some exogenous proteins seem not to be subject to retrograde axonal transport³⁴, but the reasons for this are not understood. Kuypers and his colleagues have recently shown that certain other fluorescent dyes are also subject to retrograde movement 35.36, so it is not surprising that Lucifer yellow VS serves as an effective marker for retrograde axonal transport from the chick eye to the cell bodies of neurones which have their axon terminals within the retina³³ (Fig. 5). Perhaps the dye is transported as a protein conjugate formed in situ. It is not known whether Lucifer yellow VS will prove useful for tracing connections in other parts of the nervous system.

Recently wheat germ agglutinin labelled covalently with Lucifer yellow VS (see below) has been found to provide good staining of motoneurones in the spinal cord of chick embryo after a small amount (0.5 µl of 0.5% agglutinin) was injected into leg muscles (M. McPheeters and L. M. Okun, personal communication). After retrograde transport had occurred, it was possible to dissociate the spinal cord and isolate the labelled neurones by means of a fluorescence-activated cell sorter37.

Covalent labelling of macromolecules with Lucifer yellow VS

Lucifer yellow VS labels proteins rapidly and covalently under mild conditions. In 0.1 M NaHCO₃ the reaction is complete in 2 h at room temperature. The conjugates generally have quantum yields between 0.1 and 0.2 (R. Chen and W.S., in preparation), so Lucifer-conjugated antibodies should be suitable for immunofluorescence staining. Figure 6 shows actin filaments of cultured fibroblasts stained with Lucifer-labelled antibodies. Lucifer yellow VS is similar to fluorescein isothiocyanate in its ease of use and fluorescence intensity and has the advantage that its emission peak at 540 nm is considerably to the red of fluorescein's at 515 nm, so that its fluorescence contrasts more strongly with tissue autofluorescence. But since Lucifer has no other clear-cut advantage and since less is known about the chemistry and the stability of the bond that is formed, it is likely that fluorescein isothiocyanate will remain the dye of choice for most immunofluorescence applications. When fluorescence is needed at pHs below 6, however, Lucifer yellow VS may be useful. The fluorescence intensity of Lucifer VS is unchanged from pH 2 to pH 10 (ref. 1), an unusual property for a watersoluble dye. This pH-independence makes the dye suitable for

Other uses of Lucifer yellow dyes

Among published examples of the possible uses of Lucifer yellow dyes it is worth noting that intracellular staining with Lucifer has been followed by immunocytochemical staining with rhodamine-labelled antibodies38; the goal of this approach is to characterize the immune reactivity as well as the electrophysiology of the same cell. This dye also has been used to follow changes in junctional permeability caused by moderate transjunctional polarization³⁹. Another interesting application is suggested by experiments in which an individual dye-filled neurone or even a part of a neurone was selectively damaged by means of an intense, focused spot of light²⁸. This phenomenon is sometimes referred to as "cell killing," but as the originators of the technique have pointed out⁴⁰, it is not known whether the affected cells are killed or simply inactivated temporarily. Also, it is not yet known what margin of safety there is for cells that do not contain dye. Finally, there is an interesting recent report that when turtle retina is bathed in a calcium-free Ringer's solution containing Lucifer, the bipolar cells, but not other cell types, take up dye from the medium⁴¹. Uptake is not influenced by light, but is blocked by metabolic inhibitors. It will be of interest to see whether similar phenoma occur in other neuronal

Dye-coupled systems of cells have been discovered through the use of Lucifer yellow CH^{10,11}. It has been used to monitor dye-coupling in regenerating neurones¹²⁻¹⁴, and it greatly facilitated the discovery that an electrical connection between two leech neurones was mediated by a pair of small interneurones¹⁵ and was not direct, as had previously been thought. The dye has been used to obtain information on the position of the micro-electrode tip, either in neurones¹⁶ or, in one case, in giant mitochondria¹⁷. But because of its rapid spread, presumably by diffusion, this dye generally gives only limited information on tip position, and so it may not be the best marker for this purpose.

In addition to the two sulphonated 4-aminonaphthalimides that have been used until now, more than 40 compounds in this group have recently been prepared by a convenient one-step synthesis44. These compounds have a wide range of substituents on the imide nitrogen, and most are water-soluble and have an intense yellow-green fluorescence. Because of the ease with which functional groups can be incorporated into sulphonated 4-aminonaphthalimides, these compounds will probably find new applications as biological tracers.

The experiment shown in Fig. 2 was performed at the 1978 Leech Course at Cold Spring Harbor Laboratory. I thank Elias Lazarides for carrying out the immunofluorescence staining and Kent Keyser, Enid Applegate, and Jennifer LaVail for collaboration in performing the experiments described in the legends to Figs 3, 4 and 5 respectively.

Active folding in the Algerian earthquake of 10 October 1980

G. C. P. King

Bullard Laboratories, Department of Earth Sciences, Madingley Rise, Madingley Road, Cambridge CB3 0EZ, UK

C. Vita-Finzi

Department of Geography, University College London, Gower Street, London WC1E 6BT, UK

A fold controlling the form of the local topography near El Asnam, Algeria, increased in amplitude at the time of the earthquake of 10 October 1980. The deformation occurred rapidly in an elastic-brittle manner and not in the gradual ductile fashion in which folds are normally thought to develop.

AN earthquake of magnitude 7.3 (M_s) occurred near El Asnam, in north Algeria, at 12.25 GMT on 10 October 1980. Hypocentral locations provided by the US Geological Survey (1°25′E, 36°9′N) and the International Seismological Centre (1°26′E, 36°11′N) are broadly consistent with the observed damage distribution¹ but their accuracy cannot be assumed to be better than ± 10 km. Aftershocks recorded by French² and British³ groups define a broader region 50-km long aligned broadly NE–SW with shocks having depths of up to 15 km. Extensive surface faulting occurred within this zone (Fig. 1a). A magnitude of 7.3 suggests a geometric moment⁴.5 of 2×10^9 m³, consistent with a slip area 30-km long and 12-km deep with a mean displacement of 6 m. Further work will constrain the seismic parameters more closely but is unlikely to affect the present arguments.

We examine here some of the more striking features of the surface deformation associated with the earthquake and relate them to subsurface processes. Archaeological and stratigraphical evidence is used to demonstrate that some 30 similar earthquakes could account for the local topography and geological structure.

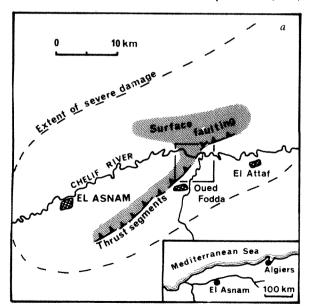

The central section of a detailed fault map of the area is shown in Fig. 1b; the complete map, which was compiled in conjunction with an aftershock study, will be published elsewhere³. A restricted area is chosen for discussion here for three reasons. First, it displays a well developed thrusting surface break which furnished a reliable measure of horizontal slip direction; and, as

this direction is consistent with that determined in preliminary fault plane solutions, the surface break probably bears a simple relationship to the seismogenic fault at depth. Second, the zone of deformation behind the fault is typical of that observed elsewhere in the area. Third, the channel and fill terraces of the Chelif river cross the section and yield information on recent and late Quaternary deformation.

Compressional faulting

In the region shown in Fig. 1b the thrust forms a clear scarp (Fig. 2) crossing fields and orchards which were level before the earthquake. Figure 3 shows the scarp cutting across one of several lines used for laying irrigation pipes in a potato field. The lines in this field show no lateral offset (excluding some disturbance close to the fault scarp) and must therefore be parallel to the horizontal component of the slip vector. The azimuth of N 140° E derived from this site was confirmed wherever the fault crossed other linear features such as irrigation channels and embankments. The form of the scarp suggests that its dip lies between 30° and 60° , a value consistent with the preliminary fault plane solution^{2,3}.

Slickensides observed near the southern end of the faulting give a spurious slip direction. This is not surprising as rock mechanics does not predict the formation of slickensides at the surface except in unusual conditions⁶. Brittle failure near the surface should always be tensile (as usually observed) and shear motion near the surface will occur only if it can exploit a very

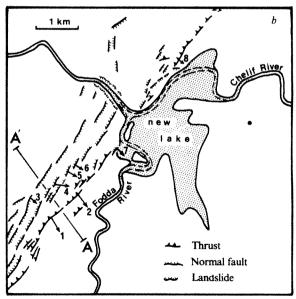

Fig. 1 a, Epicentral region showing approximate extent of severe damage, the principal segments of thrust surface breaks and the region of extensive surface faulting, most of which was tensional. b, Surface breaks near the Chelif river. Slip vector measurements: 1, 1.8 m (vertical component only), azimuth 140° E. 2, 3.2 m (vertical component only), azimuth 135° E. 3, 1.4 m (vertical component only), azimuth 130° E. 4, 1.0 m (total), azimuth 105° E, dip 50°. 5, 0.7 m (total), azimuth 125° E, dip 60°. 6, 0.7 m (total), azimuth 125° E, dip 60°. 7, 1.4 m (vertical component only), azimuth 130° E. 8, 1.2 m (vertical component only), azimuth 130°. The slip vector measurements used in Fig. 2 from section A-A' are not repeated here.

The new fault scarp is 3.2 m high.

weak pre-existing plane. If such a plane exists the slip direction will not necessarily define the broader-scale direction of shortening⁷.

Tensional faulting

Although the reverse faulting is clear and unambiguous in the section we discuss here, the most extensive and striking features of the surface deformation are tensional. In other regions, for example north of El Attaf thrusting becomes difficult to identify but tensional faulting remains obvious.

Figure 4a shows some of the tensional features to be seen when looking south-west from the vicinity of A-A' (Fig. 1b). The faults have produced a graben which seems to be reflected in the existing topography, suggesting previous motion on similar faults. Figure 4b shows a normal fault in a similar environment at the southern end of the fault system. The stratigraphic offset here is several times the displacement of 1 m caused by the present earthquake. Other examples of normal fault reactivation were also found.

Matching of opposite sides of the new tensional cracks^{6,8} showed that, despite wide variation in dip, most of the new slip vectors (including many not shown on Fig. 1b) had horizontal components close to N 140°E.

Two traverses were made across the fault zone to measure slip vectors on fault segments. One of these traverses is indicated by A-A' on Fig. 1b and the information is summarized in Fig. 5d. If no block deformation or rotation occurs between faults then a rigid-body kinematic model can be described using a displacement vector diagram as in Fig. 5c. This suggests that the net effect of hanging wall ruptures is to modify the slip vector (and hence the fault plane) such that its dip increases with depth.

Although a rigid block hypothesis is adequate to describe the surface ruptures alone, it does not explain evidence for rotation and continuous deformation; we therefore reject it. Evidence for rotation and continuous deformation is better explained by a hypothesis of fold formation. This alternative model does not demand a change in fault dip with depth and accounts for all of the observed features.

Evidence for active fold development

The deformation zone is traversed by the Chelif river (Fig. 1a,b). After the earthquake water levels reportedly rose by 5 or 6 m and formed a lake $\sim 5 \text{ km}^2$ in area. The lake was dammed not by the thrust fault scarp but by a gentle upwarp 1 km further down the valley. Before the earthquake, upwarping had already disturbed the otherwise regular trend of the river gradient. This may be observed by plotting the river profile from the 1/50,000 maps (Fig. 5a) and was noted in 1957 by Boulaine⁹, who also ascribed it to active uplift. No lake is indicated in the 1934 edition of the topographic map (Oued Fodda sheet) but a marsh is shown in the 1890 sheet occupying roughly the same area. The

marsh probably represents the remains of a lake produced in a similar way, which was completely drained by downcutting of the river channel before the 1934 map revision.

The present longitudinal profile of the river is shown in Fig. 5a which also shows the profile of a river terrace that forms a clear, continuous and dateable feature except in the region of maximum uplift. Here the river flows in a gorge¹⁰ and the terrace cannot be traced continuously. Possible terrace fragments exist within the gorge section. Boulaine identified a terrace covered with immature soils at a height of 30 m above the river⁹ (Fig. 5a) but its relation to the terrace outside the gorge cannot be established. Yet even without this information it is clear that the terrace is more uplifted than the present river profile. The uplift must have occurred after the river ceased flowing at the terrace level.

A maximum age for the alluvial deposits of the terrace is provided by Roman sites they have buried in the Chelif basin. The age of the terrace surface is at present less certain but it could be 500 yr (ref. 11). A comparison of the terrace height

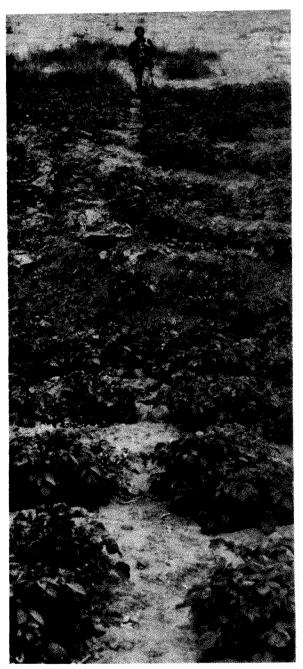

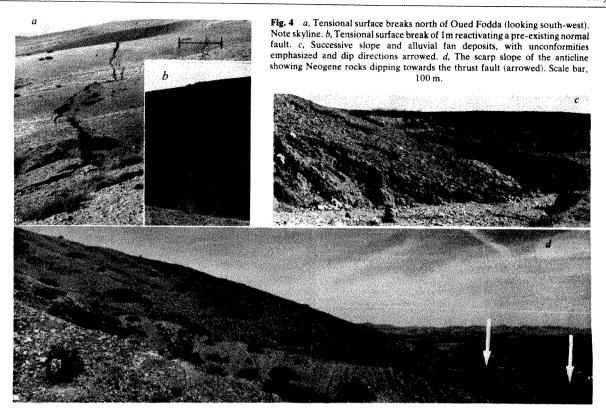

Fig. 3 The thrust scarp, here 1.8 m high, crossing a potato field. Photograph was taken along a line used for laying irrigation pipes. The line was not offset by the earthquake.

with the apparent uplift resulting from the 1980 earthquake suggests that one or possibly two earthquakes of similar magnitude have occurred since the end of deposition.

Figure 5b shows a representative structural section across the ridge. The surface breaks we have described occur at the crest and on the south-east flank of an asymmetrical anticline composed principally of late Tertiary (7 Myr) rocks. The deformation displayed by the bedrock (Fig. 5d) echoes that of the river profile and of the Chelif terrace. The steeper flank is mantled by scree and alluvial fan material. Ravines have cut through these deposits near the Chelif river to reveal three successive units (Fig. 4c), of which the oldest is nearly vertical, the middle dips about 45° and the youngest is in places nearly horizontal. The two oldest deposits contain artefacts that are Lower Palaeolithic, perhaps Acheulean, in type (Fig. 6) and therefore date roughly from the period 1-0.1 Myr ago¹². The youngest deposit contains Mousterian artefacts, which can be ascribed to the period 0.1-0.03 Myr ago¹². Deformation was therefore already in progress between these two time spans. The sequence closely resembles that of the Gafsa area in Tunisia, where conglomerates and sands containing late Acheulean artefacts with dips ranging up to 80° are overlain by alluvial deposits containing Mousterian and later industries. It is no coincidence that the Gafsa structure should also be a 'faulted fold'13

The close relationship between the tilted gravels, the thrust and the anticline north of Oued Fodda suggests that they are co-genetic. If we accept that the deformation of the Chelif terrace indicates one event and a recurrence interval of 500 yr all the topography shown in Fig. 4d could have been formed in 15,000 yr by 30 events each with an uplift of 5 m. A similar rate has been demonstrated for anticlinal uplift in the coastal Zagros¹⁴. The long chronology favoured by some archaeologists would, of course, imply longer recurrence intervals. In due course radiometric dating will remove the uncertainty.

Earthquake faulting and surface deformation

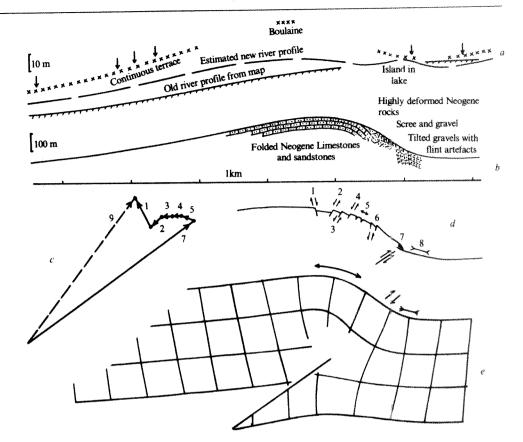

Earthquakes result from failure in rock in elastic—brittle conditions. Localized rupture at the hypocentre extends catastrophically as the rupture front expands over the fault plane until it reaches a region where the progressively increasing stress intensification resulting from increasing fault area is none the

less insufficient to fracture more rock¹⁵⁻¹⁷. The general nature of such regions remains enigmatic but certain conditions must prevail as the ruptured front of a crustal earthquake propagates downwards or towards the surface (see Fig. 7).

In regions both near the surface and at depth the rupture enters rock that is relatively stress-free before the earthquake, and fracture is driven into these zones only as a consequence of crack-tip stress. We emphasize that, so far as the rupture processes are concerned, the medium behaves in an elasticbrittle fashion and it is only over long time scales that creep relieves stress. Near the surface, stress is slowly relieved by chemical processes assisted by water flow in cracked or porous rock. These processes are suppressed at depth by confining pressure; at even greater depths thermally activated creep processes relieve stress in metamorphic conditions¹⁸. The depths that bound the elastic-brittle and elastic-brittle-ductile regions are shown in Fig. 7 as 5 and 20 km respectively. These depths are, of course, arbitrary and depend on such diverse factors as rock type, grain size, groundwater flow, thermal gradient and the recurrence period of earthquakes. The behaviour is also modified by complex fault geometry and the presence of highly incompetent layers such as salt. But, in so far as continental earthquakes rarely have hypocentres outside the range of 5-20 km and the surface ruptures of large earthquakes broadly reflect the source parameters determined from seismic observations, the model in Fig. 7 is adequate.

An implication of the model is that the rapid deformation at the time of an earthquake is elastic-brittle in nature. The ductility relieves stress created by the earthquake over a longer time scale and hence 'freezes in' the elastic deformation field produced at the time of the main shock. Following the earthquake, the relaxation of stress in the elastic-brittle-ductile zones will tend to reload the elastic-brittle zone. This reloading provides an additional or an alternative explanation for after shocks to that proposed by Das and Scholz¹⁶ who consider that stress corrosion in a brittle environment permits crack extension which leads to failure; essentially a microscopic process. The process described here will produce similar aftershock time histories but is a bulk process and depends on creep distant from the crack tip. In either case the release of strain in the aftershocks is small compared with the main shock and puts an upper limit on strain change associated with post-seismic creep. Thus

Representative sections showing faulting and deformation near the Chelif river. a, Old river profile from the topographic map, and the new river profile deduced partly from the form of the new lake. The post-Roman (Chelif) river terrace is indicated; arrows show where the height was calibrated with respect to the river profile by levelling. The terrace is a clear continuous feature arrowed the positions hetween upstream and downstream of the gorge. b, Topographical and geological section through the anticline showing the relation between the tilted gravels (as screes and alluvial fans) and the folded Neogene rocks. c, Vector diagram showing the effect of the observed tensional surface features on the slip vector at depth assuming a rigid, non-rotating, block The vectors correspond to motion on features shown in d. 1, 0.9 m, dip 60°, azimuth 100°; 2, 0.3 m dip 45°; 3, 0.3 m, dip 30°, azimuth 140°; 4, 0.5 m, dip 30°, azimuth 145°; 5, 0.2 m over many small tension cracks; 6, small bedding thrusts with negligible offsets in this particular section; 7, main thrust estimated to dip at 50°; 8, region of compression without faulting; irrigation channels in this region were telescoped by between 1 and 2m over a distance between 200 and 300m; 9, slip vector at depth. e, Deformation around a buried thrust fault with a dip of 35° and dimensionless fault parameters¹⁹ of d = 1.5, D = 1.25 I = 10 and slip of 1.15. Note that a and b have vertical exaggeration.

an elastic model approximates both the displacement at the time of the earthquake and the strain field following post-seismic stress relaxation. Modelling of the effect of ductility, which may produce long wavelength (but small strain) displacement fields will be discussed elsewhere.

Figure 5e shows the elastic deformation above a buried thrust fault. In this model the fault does not break the surface but the deformation field scarcely differs if the fault reaches the surface with diminished slip amplitude. The model is calculated using analytical finite integral expressions derived by Mansinha and Smylie¹⁹ for the displacement anywhere in a half space due to a buried dislocation surface on which displacement is specified. Figure 5e may be interpreted as representative of the deformation of a single earthquake in which strain has been exaggerated to produce a clear figure, or as an unexaggerated view of the cumulative effects of many similar earthquakes.

Assuming that the fractures represent only a small release of the total strain produced in surface materials, the position and nature of the fractures (Fig. 5d) are well explained by the model

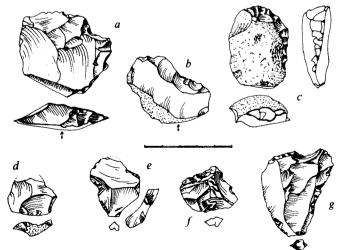

Fig. 6 Artefacts from the tilted gravels; a, b and c from the oldest unit; d, e and f from the intermediate unit; g from the youngest (ref. 11) unit. The scale is in centimetres.

in Fig. 5e. The only fractures poorly described by the model are those marked 6 in Fig. 5d and these had small displacement and were related to steeply dipping beds. This explanation of the surface features, based on a model of continuous deformation, contrasts with that offered earlier using a vector diagram (Fig. 5c), which assumes rigid unrotated blocks and requires the fault plane to steepen with depth. Although continuous deformation models in which fault dip steepens with depth would probably fit our observations, the data do not demand this refinement. The simple continuous deformation model also explains the form of the uplift of the river profile and terrace uplift (Fig. 5a). It also describes the deformation of the Neogene rocks and the present-day morphology (Fig. 5b).

Conclusions

Perhaps the most surprising aspect of the Algerian earthquake was the predominance of tensional surface faulting associated with a compressional event. This effect has been attributed to landslip motion or to changes in the dip of the main thrust plane with depth. The deformation model we present produces both extensional and compressional strain near the surface at the time of the earthquake; but, as surface materials fail more readily in tension than in compression, widespread tensional features are to be expected. The scale of the normal faulting at El Asnam is substantial and has produced major features in Neogene rocks. Thus normal faulting cannot be taken to be a fossil indicator of regional tension unless it is known to extend into the elastic-brittle zone.

The relation between structure, morphology and the location of surface breaks in the recent earthquake was clear and greatly assisted the task of fault mapping. The relation between topography and some of the surface features associated has been dismissed by many field workers as the product of large scale landslides. This view does not wholly contradict our interpretation. The elastic-ductile surface zone must retain sufficient shear strength to support the topography (or the mountains would rapidly fall down²⁰). The stresses that exist before the earthquake modulate the stress associated with the earthquake and thus, to some extent, determine where fault features are observed. In several places, tensional surface breaks increased

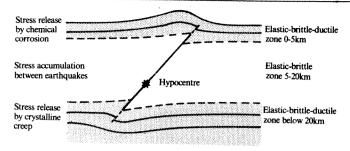

Fig. 7 The stress environment of a shallow continental earthquake.

in slip amplitude near the tops of hills and diminished in the valleys while the opposite was true of compressional surface breaks.

Although the rocks folded in this earthquake are mainly Neogene in age, the present evidence suggests that the observed folding is very much more recent. All of the folds in the region are unlikely to be this young. It is plausible that deformation has moved southwards with time and that the present fold is the frontal fold of an assemblage of serial folds21 (a view to be discussed more fully elsewhere), in which case the migration of fold activity should be regarded as the effect of serial faulting. In terms of the Jackson model of orogenic development²², this suggests that deformation in a closing sedimentary basin starts at the centre and spreads outwards.

Without suggesting that all folding is as intimately related to faulting as in the Algerian example, one is tempted by the simplicity of the proposed mechanism to regard it as widely applicable. Faults at depths formerly in the elastic-brittle region have been exhumed by erosion in sufficient numbers to account for a substantial proportion of surface folding.

Unlike the conventional view of fold formation as a plastic instability in a homogeneous stress field²³ or as a gradual process in incompetent rock above a competent faulted basement²⁴⁻²⁶ the observed folding occurs rapidly in conditions of inhomogeneous stress above and as a direct consequence of the properties of the elastic-brittle layer. The model also indicates fold formation beneath the brittle layer and, in so far as the upper and lower layers are arbitrary and time-dependent, within the brittle layer.

The mechanism of the El Asnam earthquake of 10 October 1980 ($M_s = 7.2$), the strongest recorded in northwestern Africa is compatible with a convergence between the African and European plates. The thrust is also consistent with field observations and with long period data from the global network. Aftershocks cluster around the fault trace, with a maximum depth of 12 km. Maximum vertical displacement is \sim 6 m and there is some left lateral motion. The fault trace of the 1954 earthquake at Beni-Rached was also reactivated.

THE destructive earthquake in the region of El Asnam (Algeria) on 10 October 1980 (12.25 UTC) was of magnitude $M_s = 7.2$ according to the Europeo-Mediterranean Seismological Center (CSEM) and $M_s = 7.3$ according to the US Geological Survey. Previous earthquakes have occurred in this region on 9 September 1954 with magnitude 6.7 and epicentre at Beni-Rached, and on 7 September 1934 with

epicentre at El Abadia (Carnot) 5 km north of El Attaf $(m_b = 5.0).$

The event was the largest recorded in northwestern Africa, and because of its significance to the area geodynamics, a team of French and Algerian seismologists and geologists began recording the aftershocks and mapping surface breaks within 48 h. Some of their results are reported here.

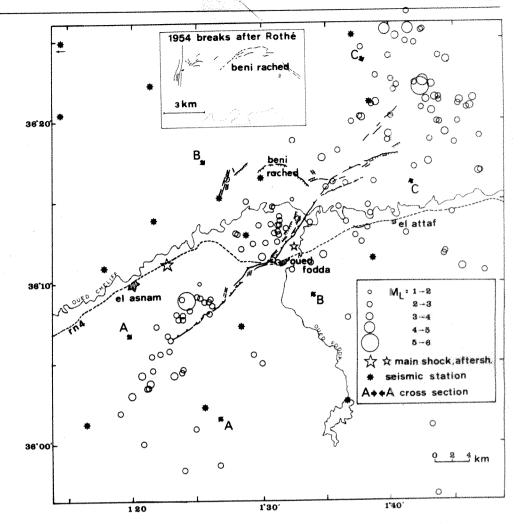

Fig. 1 Epicentres of 140 selected aftershocks (O) recorded by the local network up to 22 October 1980. A simplified map of the surface breaks is included for reference.

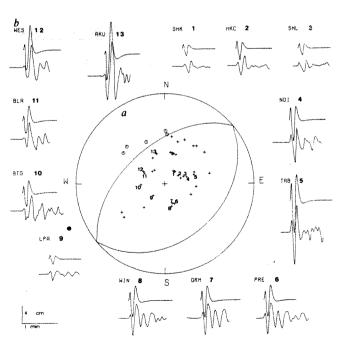

Fig. 2 Focal mechanism of main shock 10 October 1980 at 13h 25min, from long period data of the worldwide network (lower hemisphere, equal area projection). \bigcirc , Dilatations; +, compressions. The fault plane is well constrained and agrees with field observations, the auxiliary plane is less defined. The solution with no strike-slip is shown. Long period P-arrivals at different stations of the global network are shown. Theoretical seismograms (upper records) fit the first part of the signal in amplitude and phase. The numbers link seismograms to points on the focal sphere.

Geodynamics

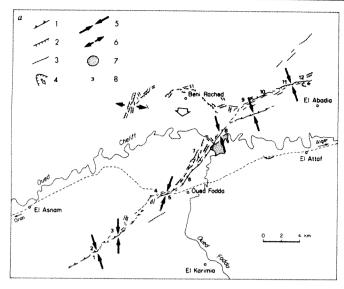

The Maghreb, like other sectors of the Western Mediterranean region has significant Quaternary tectonic movement. Recent neotectonic studies in the region have shown that the deformation is mostly compressional with associated folds, strike-slip faults, and thrusts, and a direction of shortening between N-S and NNW-SSE. This direction is compatible with the convergence of the European and African plates. Evidence of extension with direction E-W to ENE-WSW, orthogonal to the direction of shortening has also been found.

The large scale tectonics have been explained using plate tectonics and continuous deformation models^{2,3}. However, the distribution of intra-continental deformation suggested by the diffuse pattern of the seismicity and the focal mechanisms, indicate a plastic collision of continental masses without well-defined linear plate boundaries.

Effects of the earthquake

The main earthquake killed more than 3,500 people within the El Asnam district (population $\sim 900,000$). Most of the casualties occurred in the cities, although 80% of the people live in the countryside. The MKS intensity reached X in the cities of El Asnam, Oued Fodda and El Attaf. The inhabitants of the region felt small shocks as early as July 1980.

Many surface features accompanied the shock: the uplift of the northwestern block produced a natural dam ~ 4 km northeast of the city of Oued Fodda, where the Cheliff river formed a lake ~ 2.5 km² in area at the point where the Chelif river enters a canyon: landslides on the walls of the Canyon also contributed to the dam. This phenomenon shows that the river is older than many of the geological structures of the region: damming of the river may have occurred several times during the Quaternary, as shown by geomorphological evidence: for example, elevated meanders on the north-west block and thick sedimentation

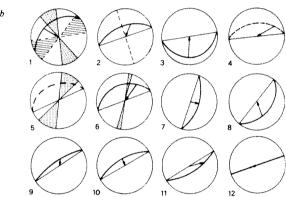

Fig. 3 a, Structural map of the epicentral region. 1, Thrust; 2, normal fault; 3, vertical cracks; 4, landslides; 5, direction of compression; 6, direction of extension; 7, flood; 8, site of slip measurements. b, Displacement vectors and striations. during the Quaternary before entering the canyon due to successive inundations. Perturbations of the flow of the Chelif river reported⁴ after the 1954 earthquake can possibly be attributed to the same cause. Detailed observations of the Quaternary sediments under the lake⁵ should enable the recurrence record of large earthquakes along the fault to be studied.

Groundwater subjected to a sudden pressure increase was ejected to the surface leaving sand blars characteristic of large earthquakes. Many natural sources were interrupted (near the fault) and others were reactivated (away from the fault).

Main shock

Relocation was used with respect to a well determined reference shock (one recorded by our local network and by the global network (8 November 1980, at 7h 54min, $m_b = 5.3$)) to obtain more precise epicentres for the main shock and the largest aftershock: values of 36°11.1'N, 1°22.8'E for the main shock, and 36°12.5'N, 1°32.0'E for the largest aftershock (10 October 1980 at 15h 39min; $m_b = 6.0$) were obtained with standard error of 1.6 and 1.5 km respectively (Fig. 1). These differ by less than 8 km from values obtained by the USGS and the CSEM. Because our method fails to provide good depth control, we regard the vertical distribution of the aftershocks which give a maximum of 12 km for the depth of the main shock and of the largest aftershock as an important constraint. The data on the focal mechanism of the main shock, from the long period stations of the global network are shown in Fig. 2a. The fault plane can be determined accurately, but the auxiliary plane is

uncertain. Our solution has no strike-slip ($\phi = 230^{\circ}$, $\delta = 52^{\circ}$, $\lambda = 90^{\circ}$), but field observations suggest that a small component of left lateral motion is present, at least in the southern part of the fault zone. Field observations also allow the seismic moment to be estimated. If we assume an average displacement of 4 m, a fault length of 40 km and a fault width of 15 km from the aftershocks distribution $\mu = 3.10^{11}$ dyn cm⁻², we obtain a seismic moment $M_0 = 7.2 \times 10^{26}$ dyn cm. A similar seismic moment of $M_0 = 4.1 \times 10^{26}$ dyn cm was also obtained by modelling long period P-wave recorded at various stations. Figure 2b compares observed and theoretical seismograms using a simple point source in an homogeneous medium and the radiation pattern given by Fig. 2a. The source function is trapezoidal in shape with a total duration of 12 s. On some of the stations (PRE, GRM. ARO, BTG, LPA) a secondary arrival is observed some 3 or 4 s after the first one. This arrival is not seen at SHK, MAT, KEV and JKF and may be due to fault propagation. The arrival times of the reflected phases led us to work with a focal depth of 3.5 km; the position of the relocalization, however, meant that this was too shallow: A more complex time function of the source leads to a greater depth: the indroduction of a sedimentary layer above the source $(v_p = 4.5 \text{ km s}^{-1})$ has little effect on the waveforms.

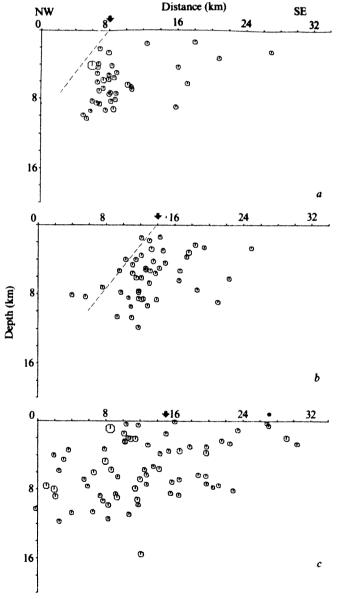

Fig. 4 Vertical distribution of the hypocentres of aftershocks at three different cross-sections (see Fig. 1). The complexity of the distribution increases from south-west (a) to the north-east (c) Dashed lines show the fault plane from teleseismic data.

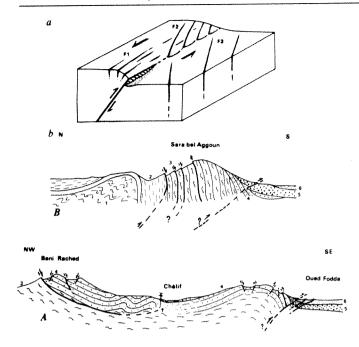

Fig. 5 a, Block diagram showing the structures at southern end of the fault. A, NW-SE section through Beni-Rached: 1, flysch; 2, medium Miocene marls; 3, higher Miocene marls; 4, Pliocene sandstone; 5, conglomerates; 6, recent Quaternary. B, N-S section through the anticline north-west of El Abadia (Fig. 3, site 10).

A stress drop of 70 bar can be estimated from the field observations using the procedure of Kanamori and Anderson⁶.

Aftershock activity

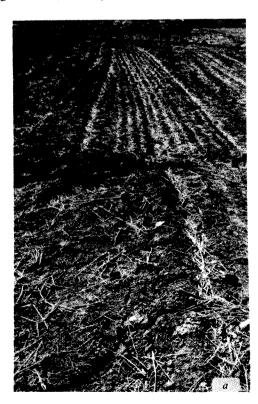

A network of 14 seismic stations (11 portable Sprenghneter MEQ-800 paper recorders and three 3-component analogue magnetic tape event recorders) were installed around the fault and operated for more than a month starting on 12 October. For clear records in conditions of strong aftershock activity, a low

gain was selected. A drum speed of 12 cm min⁻¹ was chosen and to obtain precise readings time marks were activated every second. Epicentres of 150 aftershocks within the period between 12 to 22 October 1980 (see Fig. 3) were determined using the HYPO 71 program with a layer of 3 km of 4.5 km s over an half space of 6 km s⁻¹. Most of the aftershocks correspond to local magnitude (calculated from duration) smaller than 3. There is a clear difference between the b-values at the north-east and those at the south-west side of the fault trace. For example, the station at El Tnine, (NE) recorded ~500 events per day, whereas that at Ouled Ben Abdel Kader (Massena) (SW) had only 50 events per day, the difference being smaller for the larger events located near these stations. There is clear indication of migration of seismicity at this stage of the analysis. A striking feature of the seismicity pattern is the gap in activity between the epicentres of the main shock and the city of Oued Fodda. This gap may be due to the fact that, after the main shock, most of the stress was released. Note that there is almost no seismicity around the trace of the curved fault at Beni-Rached which was activated during the 1954 earthquake. Overall aftershocks are concentrated towards the ends of the fault trace, but there is also a cluster towards the centre, north of the city of Oued Fodda.

Figure 4 shows cross-sections drawn at three places along the main fault and aftershocks contained within 11 km on each side of the cross-section projected on a vertical plane. Almost all the aftershocks have depths < 12 km, with a standard error of 2-3 km. Sections a at the south-west and b at the centre of the fault suggest a steeper fault plane than that given by the focal plane solution of the main shock. This slope is more pronounced in section a, indicating either a discontinuity or a twisting of the fault surface. Seismic activity is concentrated on the southeastern block. On the other hand the cross-section c shows a very diffuse pattern of seismicity. This area has the most complex surface breaks. The fact that a fan of surface cracks is observed suggests a multiple branching of the fault at depth at the end where the tearing stopped. This complexity might also explain the abundance of microearthquakes there compared with the smaller number of events recorded at the southwestern end.

Many records provided clear first readings and an attempt was made to construct mechanisms for the different clusters of aftershocks. Those located to the southwestern side of the fault

Fig. 6 a, The 1.30-m left lat slip measured on a ploughed at Zebadja near the centre of fault. b, Southern segment of fault. Typical pressure ric showing the uplift of the nowestern block (to the left), collapse due to gravity. Exten cracks follow the compression

trace, show a coherent composite mechanism that agrees rather well with the NW-SE compression and associated thrust of the main shock. But the data from the centre and the north-east give incoherent composite solutions. The only inference that we may draw at present is that the fault complexity seen at the surface also occurs at depth.

Tectonic structures

A large area was affected by surface fracturing (Fig. 3). The fault is relatively linear on the southern segment (N050) but it becomes wider and more complex towards the north as it approaches the hills on the right bank of the Chelif. This complex fault is superimposed on the complex geological structure of this area: the southwestern Miocene monocline gradually becomes a strongly folded and faulted structure towards the north-east (see cross-section, Fig. 5). The combined effect of rugged topography and the strong dip of layers of different strength in the folded area, may generate landslides of considerable extension and it is not easy to separate structures due to faulting from mass displacements produced by gravity. This is the case at Beni-Rached (see Fig. 3).

(1) Southern segment of the fault: the fault trace seems to be continuous in this region but a detailed analysis shows a succession of segments connected by *en échelon* cracks. There were several notable common features observed in this region.

A topographic flexure, some metres in size, with extension cracks parallel to the axis of the fold (see Fig. 5b, A) commonly occurred with the main break at the inflection point of this flexure. A striated fault plane is sometimes present. The striations indicate thrusting with an occasional left lateral motion component. At the sites with soft topography (small inclination of the fault plane near the surface) cracks (Fig. 3), some metres to tens of metres long are disposed en échelon indicating a left lateral displacement (see Fig. 5a). In all cases, outside the flexured area, we may see extension cracks that seem to be parallel to the pressure axis (Fig. 5a). In many places, where the surface soil is thick and unconsolidated (cultivated fields) the fault is recognized by a succession of pressure ridges (10-150 cm high) with the axis parallel to overall fault strike. The pressure ridges are shifted along extension cracks en échelon corresponding to transform faults. Similar surface features, which are very common along surface breaks during large shocks, were observed for the Tabas-e-Golshan earthquake7, and the Pariahuanca earthquake⁸ (Peru) (Fig. 6b).

(2) Northern segment: near the city of Oued Fodda the fault changes direction from N050 to N070 for ~3 km, and returns to N050 for ~ 10 km. At this point the fault spreads into several branches, some of which again have a N070 direction. Northwest of Oued Fodda the faulted zone is superimposed on an important topographic step, corresponding to an anticline affecting a Mio-Plio-Quaternary terrain. This anticline zone becomes N080 north of El Adabia. Here the faulting becomes more diversified and there are a large number of breaks with the aspect of normal faults. These normal faults are localized on the anticline, while below the relief there is a region of compression folds and thrusts with important displacements (up to 2.5 m) north of Oued Fodda (see Fig. 5b, A). On the other hand, motion along the segment at N070, between the lake formed by the Cheliff river and El Abadia, is modest (15-30 cm of horizontal displacement).

Normal faults within this region show different characteristics. In many cases they are the result of the extension of the surface layers of the fold (Fig. 3, site 7) or they may also correspond to the gravitational collapse of the upper block of the thrust. Those observed north of El Abadia, may result from slip along bedding planes with amplitudes of up to 3 m. This case occurs frequently in this zone, and steeply dipping beds seem to guide the deformation. Also, a fault with a 'normal' aspect on the surface may become a thrust at depth. This could be the case in Fig. 3 at points 10, 11 and 12, and Fig. 5b, A. Analogous cases of normal faults that show an aspect of reverse faults at the surface, have been demonstrated for the Thessaloniki earthquake.

More complex deformation mechanisms are observed in the folded region at the north, the whole anticline structure being affected. The left lateral component of the displacement at the south may be absorbed here. This hypothesis agrees with the progressive increase of the vertical slip towards the north-east. (3) Dislocations at Beni-Rached and Sidi Djilali: a continuous system of normal faults with large offsets extends for several kilometres near Beni-Rached in an arcuate shape near the interface between the thick limestone series of the Miocene marls and the Pliocene sandstones. This geometry suggests a large gravity slide. Several workers have described important water jets at the base of the relief at the level of the Cheliff valley, together with slow motions of the soil for several days after the main earthquakes. Note that these were the same structures that were activated during the 1954 earthquake¹⁰. The cross-section in Fig. 5b, A shows that the folds in the Pliocene layers on the right bank of the Cheliff valley may be explained by successive repetitions of the large landslides at the base of the Pliocene sandstones during the Quaternary, with the folds at the Cheliff level accounting for the extension in Beni-Rached. However, the complexity and size of the deformation mechanism means that a tectonic origin for these features is also possible. A detailed study of the aftershocks may throw some light on the nature of the tectonics at depth.

At Sidi Djilali (5-km west of Beni-Rached), the interpretation of the structures becomes more difficult. Some of the structures may be the continuation of those present at Beni-Rached, but others, corresponding to a graben parallel to the line of steepest slope have a tectonic origin. The direction of the grabens is roughly parallel to the compression axis as measured at the level of the main fault. The same interpretation may be given to certain graben to the east of Beni-Rached near the intersection with the main fault (Fig. 3). Also, a single focal mechanism corresponding to the only aftershock (8 km in depth) located at Sidi Djilali (Fig. 1), although constrained by the small number of stations, is compatible with a WNW extension of the graben.

Slip amplitude

A topographic survey conducted by the Algerian SNTF revealed important movements across the fault along the rail track from Algiers to Oran. The mean slope was 2% before the earthquake and is now 2% over 300 m. The levelling 3 days after the main shock shows that the changes are discontinuous, the largest being 6 m. The vertical displacements decrease to the South of the fault zone and disappear near the RN 19 highway (Fig. 3, site 1). To the north, vertical displacements are often larger than 1 m (2.5 m north of Oued Fodda) and reach 4 m north of El Abadia.

The amount of horizontal displacement increases from the south to the centre of the fault. It is zero at the level of RN 19 and amounts to $\sim 1.30 \,\mathrm{m}$ of left lateral slip at the centre (Zebadja) (Fig. 6a). It may reach 2.70 m to the north of Oued Fodda. It was measured by the offset of linear structures traversing the fault.

A measure of ground shortening was possible using a water duct orthogonal to the fault trace north of Oued Fodda. We obtained a total shortening of 2.2 m over 300 m—following the relative displacement of the duct with respect to the soil would give a separate confirmation of this observation—this figure provides a lower limit on shortening across the fault as the aqueduct did not cross the entire zone.

Conclusions

We have shown that, except for Beni-Rached and Sidi Djilali where gravity has a role, the nature of observed dislocations is consistent with a thrust with some left lateral slip in the South. The focal mechanism determined from long period data agrees with surface tectonics and aftershock distribution. Seismic moment calculations determined independently from local seismotectonic evidence and from long period P-data also give similar values.

The complexity of the fault increases from the south-west to the north-east, as indicated by surface evidence, aftershock distribution, the difficulty to obtain composite mechanisms, and b-value variations. The main fault, some 40 km in length which has been active during the Quaternary, is associated with folding of the Miocene, Pliocene and Quaternary formations, and is composed of segments of two different directions N050 and N070: flexure on the northwestern side of the main rupture produces a set of normal faults.

The 1980 earthquake, in contrast with the 1954 earthquake, shows a remarkable concordance between surface tectonics and seismic focal mechanisms giving a stronger constraint for plate motions. In particular, the shortening of ~2.50 m gives an upper limit to the relative motion between Africa and Europe of

A human onc gene homologous to the transforming gene (v-sis) of simian sarcoma virus

Riccardo Dalla Favera, Edward P. Gelmann, Robert C. Gallo & Flossie Wong-Staal

Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

The human genome contains a single and constant locus (c-sis) related to the transforming gene (v-sis) of simian sarcoma virus. The isolation of a recombinant phage containing the entire human c-sis gene has allowed the study of its genomic organization: c-sis extends over a region of \sim 12 kilobases (kb) which includes 1.2 kb of v-sis-related sequences interrupted by four intervening sequences.

RETROVIRUSES have been identified as the aetiological agents of naturally occurring tumours in several animal species (see ref. 1 for reviews). Furthermore, recent evidence indicates that they can sometimes be isolated from certain human T-cell leukaemias and lymphomas (see refs 2, 3 and review in ref. 4). Some of these agents rapidly induce tumours when inoculated into animals and can transform cells in vitro5. The genomes of these viruses contain sequences, called viral onc genes, which are directly responsible for transformation both in vitro and in vivo5 Substantial evidence indicates that these onc genes originated from normal cellular genes by recombination between a parent non-transforming virus and host cellular DNA5. Molecular hybridization experiments have shown that the cellular genes that gave rise to viral transforming genes are conserved throughout evolution⁵ and that their rate of evolutionary divergence parallels that of globin sequences⁶. This evolutionary conservation suggests that cellular onc genes may code for important functions in cell growth or tissue differentiation.

As these normal cellular genes are homologous to viral transforming genes, their potential role in tumorigenesis is of great interest. Several examples suggest that transformation could, in some cases, be due to an increased level of onc gene expression. In the case of the Rous sarcoma virus, the protein product of the vital transforming gene (src) is indistinguishable from that of its cellular homologue (sarc)⁷⁻⁹. The protein (pp60^{src}) is present at low levels in uninfected cells and its amount is elevated 100-fold in transformed cells⁷⁻⁹. Another cellular onc gene, c-myc, related to the avian myelocytomatosis virus (MC29) is also implicated in neoplastic transformation. B-cell lymphoma

induction in chickens by the non-acute leukosis virus (RAV-2) is sometimes associated with 'downstream' promotion of c-myc 10,11

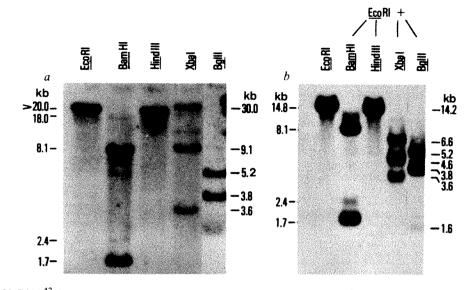

These observations underline the importance of studying the structure and function of human onc gene. Reports of preliminary experiments have confirmed the presence of some of these cellular onc genes in the human genome 6.12-14. Here we report the detection, molecular cloning and genomic organization of a newly described human onc gene (c-sis) related to the transforming gene (v-sis) of simian sarcoma virus (SSV).

The human genome contains v-sis-related sequences (c-sis)

SSV is a defective transforming virus isolated from the fibrosarcoma of a woolly monkey15,16. The genomes of both SSV and of its helper, simian sarcoma-associated virus (SSAV), were recently cloned in our laboratory¹⁷. The recombinant phages containing SSV (λ -C60) and SSAV (λ -B11) were characterized and compared with each other. The SSV genome was found to have a 1.2-kilobase (kb) insert, not shared by SSAV, which represents the viral onc gene (v-sis)17. Molecular hybridization experiments suggest that v-sis is a unique viral onc gene originating from woolly monkey DNA (F.W.-S. et al., unpublished

To investigate whether the human genome contains sequences related to v-sis, we analysed human DNA by restriction enzyme digestion and Southern blotting 18. Both SSV and SSAV were subcloned in the plasmid vector pBR322 (ref. 19) and the resultant recombinant plasmids (pC60 and pB11,

Fig. 1 Restriction pattern of c-sis in total human DNA (a) and in clone A-L33 (b). a, DNA from the human cell line HL60 (ref. 38) was prepared by cell lysis, proteinase K digestion, phenol extraction and ethanol precipitation³⁹; 20 µg were digested with 40 units of the appropriate restriction endonuclease in standard conditions recommended by the supplier. Fragments were separated by electrophoresis on a 0.8% agarose gel. DNA was denatured and transferred to nitrocellulose as described by Southern¹⁸ and hybridization was performed using dextran sulphate⁴⁰. The probe used was 2×10⁶ c.p.m. of nick-translated 18 SSV DNA (clone pC60). pC60 is a recombinant plasmid derived from λ -C60, the recombinant λ phage in which the entire SSV genome was originally cloned¹⁷. For subcloning into plasmid, the \u03b1-C60 insert was excised by EcoRI digestion, isolated on agarose gel and ligated into EcoRI-cleaved and bacterial alkaline phosphatase-treated pBR322 (ref.

41). Subclone selection was performed by colony hybridization to 32 P-labelled SSV/SSAV cDNA 42 . b, A partial AluI-HaeIII human DNA library (from T. Maniatis) 21 was screened using 32 P-labelled pC60 as a probe: 2.5×10^5 plaques were screened and one positive signal was obtained. The corresponding phage (λ -L33) was plaque-purified three times and grown in large scale 21 . λ -L33 DNA was purified and 2 μ g analysed as detailed in a. Molecular weights are in kilobases (kb).

respectively) were used to probe genomic blots of human DNA. Twelve different samples of human DNA from normal tissues, cell lines, leukaemic leukocytes and solid tumour tissues were digested with several restriction enzymes, run on agarose gel and hybridized in duplicate to pC60 and pB11 DNAs labelled with ³²P by nick translation²⁰. In all cases the same set of bands was detected by pC60 (an example is shown in Fig. 1a) but no hybridization was obtained using pB11 (not shown). The fact that v-sis is the only region of pC60 not present in pB11 indicates that human DNA contains a cellular homologue (c-sis) of the SSV transforming gene. To confirm that the hybridization was specific for v-sis, different plasmid subclones of pC60 were used as probes. Only those known to contain *v-sis* (sequences) detected some or all of the bands identified with pC60 (data not shown). Analogous results were obtained with DNAs from several vertebrate species, confirming the evolutionary conservation of c-sis 14. In all human DNAs tested c-sis is contained in a 20-25-kb fragment delimited by EcoRI and HindIII restriction sites. Within this region of DNA there are internal cleavage sites for several other restriction enzymes (BamHI, XbaI and Bg/II, Fig. 1a) and these are also conserved among different DNA samples. These data suggest that c-sis is a single-copy gene with a constant locus in the human genome.

Isolation of a recombinant phage containing human c-sis

A clone of the c-sis gene was isolated from a recombinant phage library of human DNA²¹. ³²P-labelled pC60 was used as a probe to screen 2.5×10^5 phage, corresponding to about one genome. A single recombinant phage (λ -L33) was isolated by the Benton and Davis plaque hybridization technique²². After EcoRI digestion to release the insert from the Charon 4A (Ch 4A) vector arms, the DNA was analysed by Southern blotting with the same enzymes used in the analysis of the genomic DNAs. The results are shown in Fig. 1b. Digestion with EcoRI showed a single 14.8-kb band. Ethidium bromide staining of the gel (not shown) revealed three fluorescent bands: the same 14.8-kb insert and the two vector arms (20 and 10.5 kb), indicating that λ -L33 insert has no *EcoRI* internal cuts. Thus, the size of the human DNA insert in λ-L33 is 14.8 kb. Digestion with HindIII yielded a band of 14.1 kb; an additional band of 0.7 kb visible in the gel did not hybridize to pC60. Therefore, comparison with Fig. 1a suggests that most of the EcoRI-EcoRI and HindIII-HindIII regions are present in the 14.8-kb λ-L33 insert. Within this region all the v-sis-related fragments generated by BamHI and BgIII are the same size as genomic DNA fragments generated by the same enzymes. The two XbaI sites of c-sis in genomic DNA are also present in λ -L33 as shown by the presence of three bands in λ -L33. One band (3.6 kb) in the genomic blot is identical in size to a band in λ -L33 (Fig. 1b) and the other two, corresponding to \sim 40 kb of genomic DNA, are partially represented in the 14.8-kb λ -L33 insert.

In all the enzymes tested (XhoI, SstI and PstI; not shown) there were no bands visible in the genomic blot that did not have equivalent bands in the λ -L33 blot. These data suggest that the entire c-sis is included in the clone. This was further confirmed by the facts that: (1) 32 P-labelled λ -L33 detected all the v-sis-specific fragments in a Southern blot filter containing a restriction digest of pC60 (data not show); and (2) heteroduplex analysis between λ -L33 and λ -C60 showed that the region of homology between the two clones is \sim 1.2 kb, the estimated size of v-sis (see Figs 4, 5). The availability of a clone containing the entire c-sis allowed us to study its genomic organization.

Genomic organization of c-sis

Two techniques were used to locate the regions in λ -L33 homologous to the 1.2-kb *v-sis* sequence. *v-sis*-related sequences in λ -L33 were mapped by restriction enzyme analysis

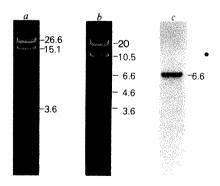

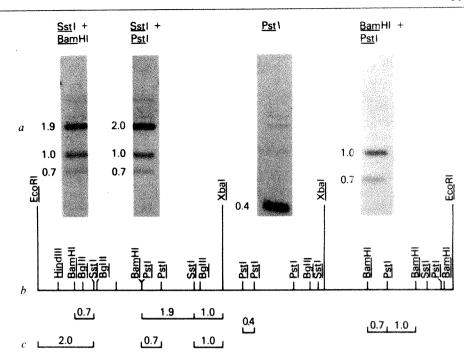

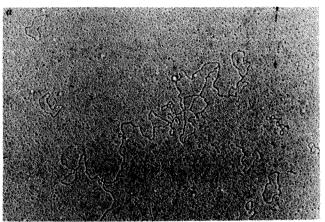

Fig. 2 $5' \rightarrow 3'$ orientation of c-sis in λ -L33. a, XbaI-digested λ -L33 DNA visualized by ethidium bromide staining. b, EcoRI + XbaI-digested λ -L33 DNA (ethidium bromide staining); 20- and 10.5-kb bands represent the left and right arms of Ch 4A, respectively. c, Hybridization of DNA from b to a probe containing the 5'-specific region of v-sis (plasmid pBG3). pBG3 was constructed by ligation of a BgIII fragment of pC60 (ref. 17), containing 0.35 kb of SSAV-related sequences and the first 5' 0.3 kb of v-sis, into BamHI-cleaved pBR322.

Fig. 3 v-sis homologous regions are fragmented in c-sis. λ-L33 DNA (100 ng)was digested simultaneously with EcoRI and XbaI restriction endonuclease. Fragments were run on a 1% agarose preparative gel. Bands at 6.6, 4.6 and 3.6 kb, corresponding to the human DNA insert, were purified from agarose by the NaI-glass powder binding method²⁴ and 100 ng from fragment were digested separately, run on a 1.4% agarose gel and transferred to duplicate nitrocellulose filters. One set of filters was hybridized to ^{32}P -pC60 DNA, the second to ^{32}P -labelled λ -L33 DNA. a, Hybridization to pC60; b, reconstructed restriction map of λ-L33 derived from hybridization of each XbaI fragment to ³²P-labelled λ-L33 DNA (blots not shown); c, brackets indicate the position of fragments (shown in a) which hybridize to pC60.

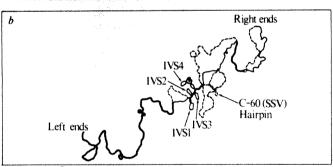

Fig. 4 Heteroduplex analysis of c-sis and v-sis. a, Electron micrograph of heteroduplex structure formed by annealing λ -L33 DNA and λ -C60 DNA. Heteroduplex formation was carried out in 50% formamide and 25 °C after alkali denaturation of caesium-banded phage particles⁴³. Heteroduplex spreading used a hyperphase of 50% formamide and a hypophase of 20% formamide⁴³. Magnification $\times 14,000$. b, An interpretive drawing of the heteroduplex structure. Intervening sequences are designated IVS 1-4 in the 5' \rightarrow 3' direction of c-sis and SSV DNA.

and heteroduplex molecules were formed between λ -L33 and the recombinant phage containing the SSV genome (λ -C60).

Restriction enzyme analysis: The orientation of c-sis in λ -L33 was determined using the endonuclease XbaI which does not cut either arm of Ch 4A (ref. 23). Digestion of λ -L33 with XbaI yielded three fragments of 26.6, 15.1 and 3.6 kb (Fig. 2a). When the human DNA insert was released from the vector arms by EcoRI digestion, the 26.6- and 15.1-kb fragments were reduced

to 6.6 and 4.6 kb, respectively, which suggests that they are linked respectively to the left (20 kb) and right (10.5 kb) arm of Ch 4A (Fig. 2b). The 3.6-kb band is conserved in both digestions; thus this fragment is not linked to vector arms and is located centrally in the λ -L33 insert. To determine the $5' \rightarrow 3'$ orientation with respect to the sis coding sequences, EcoRI-XbaI-digested λ-L33 DNA was hybridized to a probe specific for the 5' region of v-sis. Only the 6.6-kb fragment hybridized to this probe (Fig. 2c). Thus the data suggest that the orientation of XbaI fragments in λ-L33 is: (Ch 4A left arm)-5'-6.6 kb-3.6 kb-4.6 kb-3'-(Ch 4A right arm). For simplicity we mapped each XbaI fragment separately after isolation on a preparative agarose gel²⁴. Restriction digests of each fragment were used to make duplicate Southern blots to hybridize to 32P-labelled λ-L33 or p-C60 DNA. λ-L33 bands (not shown) allowed the construction of the map shown in Fig. 3b.

The v-sis-related bands are shown in Fig. 3a for each of the three fragments. These bands represent sequences of homology in five noncontiguous regions (bracketed in Fig. 3c). Fragments detected by λ -L33 but not by pC60 represent DNA consisting only of sequences unrelated to v-sis. In the case of the internal XbaI fragment these must be due to intervening sequences interrupting v-sis-related regions. Both intervening sequences (that is, between hybridizing regions) and flanking cellular sequences are present in the 5' and 3' XbaI fragments of c-sis.

The restriction enzyme analysis suggests the presence of five v-sis homologous regions interrupted by four intervening sequences. To analyse further this structure, electron microscopic studies were performed.

Heteroduplex analysis: Human c-sis, cloned in Ch 4A, and the 6.3-kb SSV genome, cloned in Ch 21A (Ch 21A) (ref. 17), were compared by heteroduplex formation. A typical molecule is shown in Fig. 4. The left arm of Ch 21A (C60) is 21.2 kb, of which 19.8 kb from the end are identical to the entire left arm of Ch 4A (L33) (ref. 23). Two portions of the right arms are the same²³ and form an interrupted duplex. The hairpin loop structure in λ -C60, formed by the self annealing of a direct and inverted long terminal repeat (LTR)17, provides a convenient marker for locating v-sis at the 5' side of the hairpin. Here a region of hybridization (~1.3 kb) between λ -C60 and λ -L33 can be seen. This region contains four deletion loops which represent sequences in the λ -L33 insert nonhomologous to v-sis. As they are between regions of homology they are most likely the four intervening sequences identified in the restriction enzyme map. Between the left arm area of the vectors and the region of homology there is a substitution loop formed by the 5'-flanking cellular sequences of λ -L33 (which do not hybridize to the SSV helper sequences 5' of v-sis) and the remaining 1.4 kb of the Ch 21A left arm not included in the Ch 4A left arm. A large substitution loop 3' of v-sis includes SSAV-related sequences of C60 and the Ch 21A right arm facing λ -L33 flanking cellular sequences and the Ch 4A right arm. Measurements and orientation of the left substitution loop, duplex regions and the deletion loops (Fig. 5) are consistent with the map derived from the restriction enzyme analysis. A general scheme of the genomic arrangement of c-sis is shown in Fig. 5.

Repeated sequences in c-sis introns

In heteroduplex experiments, λ-L33 single-stranded molecules showed various secondary structures. Furthermore, when λ-L33 was used as a probe in genomic blot experiments with human DNA, a hybridization smear was visible (data not shown). These observations prompted us to check the presence of repeated sequences in λ -L33, specifically, the Alu family of interspersed repeats because most repeated sequences in the human genome belong to this family²⁵. Accounting for 3-5% of human DNA, the Alu family consists of several 300-base-paired fragments bearing a single AluI site25. A recombinant plasmid (BLUR 8) containing a 300-base pair Alu repeat insert25 was used as a probe to ascertain the presence of these repeats in λ -L33. Several regions of hybridization were seen in restriction digests of λ -L33 DNA (data not shown). To locate the repeats more precisely, each XbaI fragment was mapped as previously described. Results are shown in Fig. 6b. Segments containing Alu repeats are located in three separate regions included in two different intervening sequences. Their approximate positions are also shown in Fig. 5.

Discussion

Vertebrate genomes contain nucleotide sequences homologous to the transforming genes of oncogenic retroviruses $^{5.6.12-14.26.27}$. Our study extends this observation to the cellular homologue of v-sis, a newly characterized viral transforming gene 17 , most likely originated from woolly monkey DNA (F.W.-S. et~al., unpublished data). We report elsewhere 14 that c-sis is conserved among vertebrate species and here we describe the characterization of the c-sis locus in the human genome. Our data suggest that v-sis homologous sequences are present in a single and constant locus in human DNA. This locus showed no polymorphism in our analysis of 12 different DNA samples. c-sis consists of a DNA sequence 12 kb long where 1.2–1.3 kb of v-sis homologous sequences are interrupted by four intervening

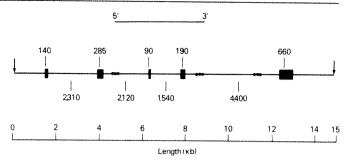

Fig. 5 A schematic representation of the organization of c-sis sequences in $\lambda\text{-}L33$. The lengths of the v-sis homologous regions (black boxes) and intervening sequences (solid lines) are mean values derived from measurements of at least six heteroduplex structures. Standard deviations range from $\pm 5\%$ for the larger to $\pm 15\%$ for the smaller measurements. Charon 4A DNA sequences are not shown here; arrows indicate the ends of the cloned genomic fragment. $\bullet \bullet \bullet$ Indicate the approximate position of repeated sequences of the human Alu family (see text and Fig. 5). kb, Kilobases.

sequences. The presence of intervening sequences has been shown in all but one case by studies of cellular *onc* genes from the species of origin of the respective retroviruses. Examples are the cellular *onc* genes of Abelson leukaemia virus in mice, of Harvey sarcoma virus in rats, Rous sarcoma virus and avian erythroblastosis virus in chickens, and feline sarcoma virus in cats ^{13,26}. Although *v-sis* is not originated from human DNA, the general structure of *c-sis* has been preserved throughout evolution, which suggests that it may represent a functional gene in man. If *c-sis* and *v-sis* code for a similar protein as in the Rous sarcoma system⁹, the intervening sequences would represent noncoding regions (introns) which would be excised during RNA processing.

A separate observation reported here is the presence of repeated sequences related to the Alu family of repeats in c-sis introns. The significance of this finding is unknown. Members of this family of repeats are estimated to be present $\sim 300,000$ times throughout the human genome²⁵. They have been found at the 5'- or 3'-flanking region of several genes and in the intergenic region of gene clusters, as in the case of the human β -globin gene family²⁸. However, their inclusion in intervening sequences has not been reported. Preliminary data from our laboratory suggest that the human onc genes related to feline sarcoma virus (c-fes) and avian myelocytomatosis virus (c-myc) also contain Alu repeated sequences. Further experiments will be required to determine the exact location of these repeats in

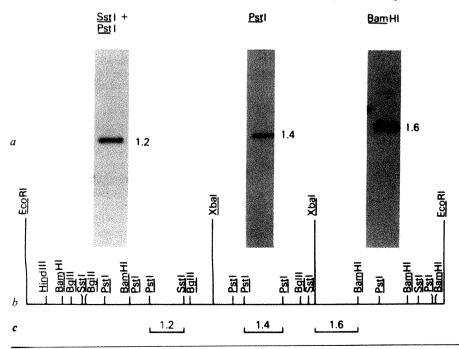

Fig. 6 Mapping in λ-L33 of repeated sequences homologous to the human Alu family. a, λ-L33 Xba fragments of DNA were prepared as described in Fig. 2 legend and each fragment was hybridized to BLUR 8 DNA²⁵. the different cellular onc genes and their role, if any, in onc gene expression.

Thus far, the protein product of either v-sis or c-sis has not been fully characterized. Many of the known retroviral transforming proteins are kinases which have the unusual property of phosphorylating tyrosine residues²⁹⁻³⁴. Furthermore, recent studies indicate that some of these viral onc gene products are structurally and functionally similar to cellular protein kinases involved in the regulation of the (Na⁺ + K⁺)ATPase pump (M. Spector and E. Racker, personal communication). It is of interest to test whether other onc genes, including c-sis, are involved in this basic metabolic pathway. In preliminary experiments we used cloned SSV DNA bound to nitrocellulose to select v-sisspecific mRNA from SSV-transformed non-producer cells. In vitro translation of this mRNA resulted in the synthesis of a protein of molecular weight 20,000 (V. Manzari et al., unpublished data). This product could account for the coding potential of c-sis and experiments are now being done to characterize the protein.

Substantial evidence suggests involvement of cellular onc genes in neoplastic transformation. Increased levels of expression of any of these genes may be the common mechanism in pathogenesis of different types of tumours. This hypothesis is

substantiated by both in vitro and in vivo experiments. In vitro experiments performed with mouse c-mos, the cellular homologue of Moloney sarcoma virus²⁷, showed that this gene acquires transforming activity when linked to promoter sequences from the murine leukaemia virus genome²⁷. In vivo, B-cell lymphomas in chickens are characterized by abnormal expression of another cellular onc gene, c-myc 10-11. As these genes are conserved structurally and functionally among diverse species it is conceivable that they are also targets for tumorigenesis in man. There is evidence that mutation at certain loci is associated with specific human malignancies35. Moreover, it has been recently reported36,37 that DNA from certain human tumours have transformation activity in vitro involving specific, possibly unique genetic loci. Complete definition of the family of human onc genes will allow us to investigate whether any are involved in the pathogenesis of human aumours. The detection and molecular cloning of the human c-sis gene has allowed us to initiate these studies.

We thank Dr T. Maniatis for supplying us with the human DNA library, Dr C. W. Schmid for the BLUR 8 recombinant plasmid and Stefano Martinotti for help with the restriction mapping data.

During the past 15 yr a small but remarkable collection of cosmological conundrums have been identified; each apparently independent, but probably all inter-related at a deeper level than existing theories have penetrated. The outstanding problems are of explaining the observed isotropy, homogeneity, flatness and specific entropy of the Universe¹. Good explanations for the last of these have recently emerged^{2,3} from the study of C, CP and baryon nonconserving interactions which arise in grand unified gauge theories (GUTs) of the strong and electroweak interactions. Recently, Guth has discussed the inflationary Universe as a possible natural explanation for the observed large-scale homogeneity and near critical density ('flatness') of the Universal expansion⁴. We show that one cannot ignore the first conundrum—the isotropy; a Universe

with a large amount of anisotropy will not undergo the inflationary phase. A Universe with only moderate anistropy will undergo inflation and will be rapidly isotropized. Other consequences of the inflationary Universe are discussed.

The three specific problems which we shall refer to are: the isotropy problem; the homogeneity-horizon problem; and the flatness problem.

The isotropy problem is exhibited by the observed structure of the 2.9 K microwave background radiation⁵. The temperature distribution of this primordial radiation field is isotropic to high precision⁶, $\Delta T/T \leq 10^{-4}$ over large angular scales, $\theta \geq 7^{\circ}$. All attempts to explain this present isotropy as a consequence of classical dissipative processes acting during the early stages of the Universe have been unsuccessful and they are opposed in principle by various general arguments⁷⁻⁹. Despite being an unstable property of physically realistic cosmological initial conditions, isotropic expansion is a property of the observed Universe. It is not yet clear whether particle production at $t \sim 10^{-43}$ s will help resolve why the present level of isotropy exists and when it arose because some anisotropies grow up again after the Planck time and some anisotropic plane wave universes create no particles 10-12.

The homogeneity-horizon problem falls into two parts. On the one hand, the microwave and X-ray radiation backgrounds,

and the radio source counts^{6,13}, all provide evidence for a striking level of large-scale spatial homogeneity on scales >~1 Gpc. But on the other, we see that luminous material is clustered into discrete inhomogeneities of characteristic sizes. Statistical studies⁶ of galaxy clustering indicate the existence of a universal clustering scale, $\sim 10^{15} M_{\odot}$, which divides the developed (non-linear) small-scale structure of galaxies and clusters from the smooth background. On dimensions exceeding the encompass of $\sim 10^{15} M_{\odot}$ the observed structure fades away into increasing homogeneity on larger and larger scales. Explaining the origin of small-scale inhomogeneity in the form of galaxies whilst simultaneously explaining the smooth underlying background on very large scales is the homogeneity problem. This problem is compounded by the presence of horizons¹⁴ in known cosmological solutions to Einstein's equations. In the Friedmann model during the radiation-dominated epoch, the total mass of baryons within a causally coherent region of volume $\sim (ct)^3$ at time t after the 'bang' is only $M_{\rm H} \sim (t/1{\rm s})^{1.5} M_{\odot}$. This ensures that causal processes can only smooth out irregularities over the small scale $M_{\rm H}(t)$ at early times. By the same token, the spontaneous generation of small inhomogeneities during phase transitions or other non-linear events is limited to the scale $M_{\rm H}(t)$. To explain the large-scale homogeneity or small-scale inhomogeneity, rather than treat them as initial data, it is necessary (but not sufficient) to find mechanisms which can remove or considerably inflate the horizon size during the very early $(t \le 10^{-4} \text{ s})$ stages of the Universe. This is the horizon problem.

有多数形容

It is still an open question whether or not the Universe contains sufficient material to begin recollapsing at a finite time in the future. One reason why this question has proved so difficult to resolve observationally is the 'flatness' problem⁴. The Universe is expanding very close to the intermediate (Einsteinde Sitter) model which contains the critical matter density and so just sufficient expansion energy to expand to infinity. To evolve the observed proximity to the flat (=Euclidean space sections) Einstein-de Sitter model, deviations from the critical density must have been smaller than one part in 10^{57} at the Planck time,

$$\left(\frac{\rho - \rho_{\rm cr}}{\rho_{\rm cr}}\right)_{\rm fp} \leq 10^{-57}$$

This remarkable degree of fidelity constitutes the flatness problem. Another way of phrasing it is: although the only natural time scale in the gravitation theory is $t_{\rm p} \sim 10^{-43}$ s, the Universe has expanded for $\sim 10^{60}$ $t_{\rm p}$ without either recollapsing or entering the Milne (negative) curvature-dominated phase.

Recently, Guth⁴ has suggested a possible resolution of the horizon-homogeneity and flatness problems—the so-called inflationary Universe. In his picture, owing to the slowness of the GUT phase transition at $t_{\rm GUT} \sim 10^{-35}$ s the Universe undergoes a period of de Sitter expansion during which the (particle) horizon grows exponentially with time and the spatial curvature decreases relative to the matter density, also exponentially, thereby explaining two of our conundrums.

In the Friedmann model the expansion scale factor, R(t), is governed by⁵, $(\hbar = c = k_B = 1)$;

$$\frac{\dot{R}^2}{R^2} = \frac{8\pi G}{3} (\rho_r + \rho_0) - \frac{k}{R^2}$$

$$= \frac{4\pi^3 G}{45} g_*(T) T^4 + \Lambda - \left(\frac{k}{R^2 T^2}\right) T^2 \tag{1}$$

where ρ_r is the radiation energy density which equals $g_*(T)\pi^2T^4/30$, $g_*(T)$ is the total effective number of degrees of freedom of all relativistic species at temperature T (= $\Sigma_{\rm bosons}$ g + 7/8 $\Sigma_{\rm termions}$ g), ρ_0 is the vacuum energy density associated with the cosmological constant, $\Lambda = 8\pi G \rho_0/3$, and $k = \{\pm 1, 0\}$ is the space-time curvature signature⁵. We know today that the cosmological term is small, $\rho_0 < 10^{-30}$ g cm⁻³. However, in particle physics theories which undergo spontaneous symmetry breaking (SSB) the Lorentz invariant energy density associated

with the vacuum changes during a phase transition and creates an effective cosmological constant, $\rho_0 \sim {\rm O}(T_{\rm c}^4)$, where $T_{\rm c}$ is the critical temperature of the phase transition. In GUTs the symmetry of the theory breaks down at a temperature ${\rm O}(10^{15}~{\rm GeV})$ leaving an induced cosmological constant and associated vacuum energy density ${\rm O}(10^{77}~{\rm g~cm}^{-3})$ —unless one specifies an initial compensatory cosmological term of exactly the same magnitude but opposite sign. In this case, at temperatures above $T_{\rm c}$ we have $\rho_0 \sim (10^{15}~{\rm GeV})^4$, but below $T_{\rm c}$ the cosmological term is zero—the initial cosmological term and the vacuum energy density associated with SSB precisely cancel.

As the Universe cools below T_c , bubbles of the low-temperature (broken) phase nucleate and grow, and eventually the entire Universe is in the broken phase. However, Guth⁴ pointed out that if the nucleation rate is sufficiently small, then the Universe will remain in the high-temperature (symmetric) phase for a non-negligible period: the 'false vacuum' is metastable. During this interval the initial cosmological term, ρ_0 , remains uncancelled and soon begins to dominate the expansion dynamics, $\rho_0 > \rho_r$. The Universe undergoes a phase of de Sitter expansion, $R \propto \exp\left(\Lambda^{1/2} t\right)$ with $T \propto R^{-1} \propto \exp\left(-\Lambda^{1/2} t\right)$ and 'supercools' (the Universe remains in the symmetric vacuum until a temperature $T_s \ll T_c$). Finally, the transition is completed $(t = t_* \geqslant t_{\rm GUT}$ and $T_s \sim T_c \exp\left(-\Lambda^{1/2} t_*\right) \ll T_c$); the initial ρ_0 term is cancelled and the Universe is reheated to nearly T_c by the latent heat release. The expansion then resumes Friedmann behaviour. (The graceful return to a Friedmann model remains a difficulty⁴.)

Just before the transition occurs, $(T \ge T_c)$, one might expect that because t is not too different from $t_p \sim 10^{-43}$ s, (the only natural time scale in the theory), the curvature term (k/R^2) would be $\sim O(\rho_r)$ (the flatness problem). In addition, if the baryons were created (or already present) at this time, then there would be only about one baryon per horizon volume. Guth⁴ points out that if the inflationary phase lasts long enough to supercool by a factor $\sim 10^{28}$ ($t_* \sim 65 \Lambda^{-1/2} \sim 65 t_{\rm GUT}$), then when Friedmann behaviour recommences: (1) the curvature term will have been reduced relative to the radiation density by a factor $\sim 10^{56}$ ($T_* \sim T_c$, while R has inflated by 10^{28}) so solving the flatness problem; and (2) the horizon has grown large enough to encompass the portion of the Universe accessible to us today $\ge 10^{22} M_{\odot}$. Thus if the Universe was smooth on scales of the horizon at $t_{\rm GUT}$, the horizon problem is solved.

The question naturally arises as to whether nucleation is slow enough to allow such supercooling. The probability that a given point remains in the unbroken phase is (ref. 4, equations 3.14/.15)

$$p(t) = \exp\left\{-\int_{0}^{t} dt_{1} \lambda(t_{1}) R^{3}(t_{1}) V(t, t_{1})\right\}$$
 (2)

where

$$V(t, t_1) = \frac{4\pi}{3} \left(\int_0^t \frac{\mathrm{d}\theta}{R(\theta)} \right)^3$$

and λ is the nucleation rate which, if one assumes that $\lambda(t) = \lambda_0$ and $R \propto \exp(\Lambda^{1/2} t)$, then implies $p(t) = \exp(-t/\tau)$ where $\tau = 3\Lambda^{3/2}/4\pi\lambda_0$. In principle λ_0 can be computed and Guth states that because $\lambda_0 = A\rho_0 \exp(-B)$, one can easily obtain $\tau \approx t_* > 65\Lambda^{-1/2}$; (note, $A \sim 0(1)$ and B is a barrier penetration term).

This analysis relies on the assumption of Friedmann expansion for R(t); that is, it resolves the homogeneity-horizon and flatness problems by ignoring the isotropy problem. The Friedmann model is already isotropic and homogeneous. It is argued that particle physics processes homogenize the Universe on scales $\leq ct_{\text{GUT}}$ so the Universe can be assumed 'patchwise' homogeneous. However, the tacit assumption of some degree of isotropy remains. We shall show that if it is relaxed the inflationary phase can be prevented.

If the very early Universe were anisotropic then a good description of its expansion dynamics is provided by a generalized Friedmann equation¹⁵ for the (geometric) mean scale factor

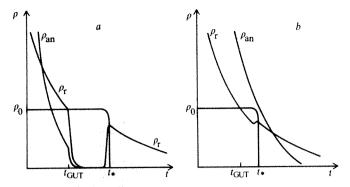

Fig. 1 The contributions to the right-hand side of equation (3) are shown as a function of time. a, If $\rho_{\rm an} \leq \rho_0$ at $t_{\rm GUT}$, the inflationary phase will ensue and both $\rho_{\rm r}$ and $\rho_{\rm an}$ decrease exponentially. When the phase transition is complete, $t=t_*$, the latent heat release increases $\rho_{\rm r}$ to $\sim T_{\rm c}^4$. $b_{\rm r}$ If $\rho_{\rm an} \geq \eta^{1/2} \rho_0$ at $t_{\rm GUT}$, the inflationary phase does not occur, and the Universe continues to be anisotropic. When the transition is complete, there is a latent heat release increasing $\rho_{\rm r}$ slightly. The anisotropy is always decaying adiabatically $(\rho_{\rm r}/\rho_{\rm an} \sim R^2)$, eventually becoming negligible.

R(t),

$$\frac{\dot{R}^2}{R^2} = \frac{8\pi G}{3} (\rho_r + \rho_0) - \frac{k}{R^2} + \frac{\Sigma^2}{R^6}$$
 (3)

where $\rho_{\rm an}=\Sigma^2R^{-6}$ is the anisotropy (gravitational wave) 'energy density'. Equation (3) is exact for space-times which possess isotropic three-curvature and an excellent approximation to those that do not over short-time intervals. In equation (3) the constant Σ is arbitrarily fixed by the initial data. When $8\pi G\rho/3 < \Sigma^2R^{-6}$ the cosmological model is called anisotropic and will have an overall expansion rate, $R \propto t^{1/3}$, which differs from the isotropic radiation model, $R \propto t^{1/2}$. We can choose a class of anisotropic models which have Σ large enough to remain anisotropic until any pre-specified epoch. The isotropy problem can be thought of as explaining why Σ must be chosen to be 'small'. All anisotropic models described by equation (3) eventually isotropize as $\rho_r/\rho_{\rm an} \propto R^2$. They will only have isotropized by $t_{\rm GUT}$ if Σ is specially chosen.

If the Universe expands anisotropically at $t_{\rm GUT}$ then we can solve equation (3) to obtain a description of the competition between anisotropy and vacuum energy (Λ)

$$R^3 = \frac{\Sigma}{\Lambda^{1/2}} \sinh \left(3\Lambda^{1/2} t \right) \tag{4}$$

We obtain the Kasner anisotropic behaviour, $R \sim t^{1/3}$, when the anisotropy dominates $(t \to 0)$ and de Sitter, $R \sim \exp{(\Lambda^{1/2} t)}$, when the vacuum energy dominates $(t \to \infty)$.

If the anisotropy energy density $\rho_{\rm an}$ is less than $\rho_0(\sim \rho_r)$ at $t_{\rm GUT}$, then the inflationary phase will proceed (Fig. 1a). In addition $\rho_{\rm an}$ will decay adiabatically as exp $(-6\Lambda^{1/2} t)$, rapidly degrading any anisotropies. However, if $\rho_{\rm an} > \rho_0$ at $t_{\rm GUT}$, then the Universe will continue to be anisotropic with $R \propto t^{1/3}$ and $\rho_{\rm an} \propto t^{-2}$. If the transition is slow enough, then $\rho_{\rm an}$ may fall below ρ_0 and an inflationary phase would ensue. To address this issue consider p(t) given by equation (1). For $R \sim t^{1/3}$ we find

$$p(t) = \exp(-t/\tau) \tag{5}$$

$$\tau = \frac{80}{9\pi\lambda_0 t^3} \tag{6}$$

In computing τ we have assumed spherical geometry, although the actual geometry is nonspherical. With Kasner geometry τ is smaller by a geometric factor of 0(10). Therefore, we shall use $\tau = 1/\pi\lambda_0 t^3$ rather than equation (6). Unlike the inflationary case, where $\tau = 3\Lambda^{3/2}/4\pi\lambda_0 \approx 3/4\pi\lambda_0 t_{\rm GUT}^3$ the nucleation time scale τ decreases as $\sim t^{-3}$ so that $t_* \sim (\pi\lambda_0)^{-1/4}$. Suppose that in the absence of anisotropy $t_* = \eta t_{\rm GUT}$, then in the presence of anisotropy $t_* \approx \eta^{1/4} t_{\rm GUT}$. During the time between $t_{\rm GUT}$ and t_* , $\rho_{\rm an}$ will have decreased by a factor $(t_*/t_{\rm GUT})^2 \approx \eta^{1/2}$. For $\eta \sim 65$,

(the value required to resolve the horizon problem in the isotropic model⁴), $\rho_{\rm an}$ has only decreased by a factor ~ 10 by t_* . That is, if $\rho_{\rm an} \ge 10\rho_0$ at $t_{\rm GUT}$, then the anisotropy will prevent the occurrence of the inflationary phase (Fig. 1b). The value of the nucleation rate λ_0 is very uncertain, so that η might be $\gg 65$ or $\ll 65$; in any case, one must not separate the question of isotropy from the homogeneity-horizon and flatness problems.

The inflationary Universe was motivated, at least in part, by the flatness and homogeneity-horizon conundrums. However, the isotropy problem must also be considered. The presence of a large amount of initial anisotropy $\rho_{\rm an}(t_{\rm GUT}) \ge \eta^{1/2} \rho_0(t_{\rm GUT})$, will prevent the de Sitter phase from occurring and will decay away adiabatically thereafter ($\propto R^{-6}$). The pressure of this anisotropy at $t_{\rm GUT}$ will not prevent baryosynthesis, and in fact allows for the production of isothermal perturbations highly desirable for galaxy formation highly desirable for galaxy formation of the 2.9 K background.

If the inflationary phase were to occur there would be some interesting consequences. Any relics from an earlier epoch are effectively erased. For example, any initial baryon or lepton number is deleted (hence baryosynthesis must occur after the inflation which is not a difficulty as the Universe is reheated to $\sim T_c$); any gravitons emerging from t_p will have their density degraded relative to photons by a massive factor $\exp(3\Lambda^{1/2}t_*) \sim 10^{83}$ because the latent heat release will not couple to the collisionless graviton sea. Recently, Starobinskii 18.19 has pointed out that the graviton background arising from a cosmological model with a de Sitter expansion before t_p (not arising from a phase transition) is potentially detectable at a frequency of $\sim 10^{-4}$ Hz. If this radiation were detected it would exclude the inflationary process by showing that the primordial graviton density is not $\sim 10^{80}$ times smaller than the photon density.

It also seems that, whilst solving the horizon problem, the inflationary Universe may compound the part of the homogeneity problem which seeks an explanation for the existence of small inhomogeneities and thereby galaxies. Any curvature fluctuations (spatial variations in k/R^2) imprinted on the dynamics before t_{GUT} would have their effective amplitudes reduced by $\sim \exp(2\Lambda^{1/2} t_*) \sim 10^{56}$. A new spectrum of adiabatic inhomogeneities would have to be produced when the phase transition is completed (note, anisotropies in the spatial three curvature are also reduced during the de Sitter phase). In essence the inflationary Universe cleans the slate, and the Universe is reborn. Elsewhere 16 we have described a way of generating isothermal fluctuations during this epoch. The process of bubble nucleation and percolation is inhomogeneous and might provide a mechanism for creating new fluctuations: for example, bubble wall collisions might produce large-scale inhomogeneous shear, which in turn can give rise to isothermal perturbations16. However, owing to its extremely chaotic nature these fluctuations might be of such large amplitude on all scales up to the inflated horizon size $\ge 10^{22} M_{\odot}$, that a profusion of black holes would result, rather than a regular Poisson spectrum.

In the Guth hypothesis⁴ the explanation of the flatness, and homogeneity, problems is tied to that of the isotropy problem. The web of interconnections may be far more extensive: a theory of quantum gravity may reveal them all to have a common origin^{10,11}. An interesting inter-relationship is already known at the classical level. It has been shown^{8,20} that the set of homogeneous initial data giving rise to open isotropic universes asymptotically is of measure zero in initial data space but the set which gives rise to flat, isotropic Universes is not of measure zero. When the initial anisotropy of the Universe is not too large, the inflationary Universe can exist and explain the flatness we observe. This case is an interesting contrast to the result of Collins and Hawking: inflated universes will be flat if they are isotropic.

Evidence for sulphur implantation in Europa's UV absorption band

Arthur L. Lane, Robert M. Nelson & Dennis L. Matson

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA

The International Ultraviolet Explorer (IUE) spacecraft has obtained observations of the galilean satellites over the past 2 years which fortuitously span the periods of the Voyager encounters with the jovian system. Our IUE observing programme is designed to determine the UV spectral characteristics of the galilean satellites as a function of orbital position, largescale areal variability and temporal dynamics. During the past year we have concentrated on the albedo variations of each body^{1,2}. We report here the discovery of an absorption feature at 280 nm in Europa's reflection spectrum. Observations with the IUE show that this absorption is strongest on Europa's trailing hemisphere (central longitude 270°). We identify the feature as an SO₂ absorption band and hypothesize that SO₂ may form when energetic jovian magnetospheric sulphur ions are injected into Europa's water-ice surface.

Initial analysis of the Europa spectra² showed a substantial near-UV (250-320 nm) albedo difference when comparing the leading (central longitude 90°) and trailing (central longitude 270°) hemispheres. This effect has been reported previously on the basis of ground-based observations³⁻⁵. In view of these earlier discoveries we did not consider the near-UV behaviour as anomalous. A more detailed examination of the low-resolution (~1.1 nm FWHM) IUE spectra showed a pronounced decrease of disk-averaged albedo towards shorter wavelengths (3,250-2,600 Å). The decrease was observed for both the leading and trailing hemispheres. To improve the signal-to-noise ratio, several spectra from the same hemispheres (orbital longitudes) were summed. These pairs of summed spectra represent the extrema of the visible and UV albedo variations. These sets were then ratioed to each other. For Europa, spectra at orbital longitudes between 84° and 104° were used for the leading side and between 270° and 281° for the trailing side. For comparison, a set centred near 90° and 270° was selected for Ganymede (see Fig. 1). Noise which results from partial pixel misregistration and from small wavelength drifts in the extracted data from the IUE image tube has not been filtered or smoothed. Therefore,

we present a 'worst-possible' case for the credibility of the ratioed spectra. Unlike the trailing/leading side comparison for Ganymede which demonstrates an additional darkening with decreasing wavelength on the trailing side relative to the leading side, the Europa ratio has a definite absorption band centred near 280-290 nm. Modest amplification of the Ganymede ratio to the noise limit of the data shows no similar band.

The shape of the Europa absorption band suspiciously similar to the absorption spectrum of the $\tilde{A} - \tilde{X}$ UV band of SO₂ centred between 280 and 290 nm (ref. 6). This portion of the SO₂ absorption spectrum is also presented in Fig. 1. The alignment and shape of the vapour-phase SO₂ absorption spectrum is an excellent match to the observed absorption on the trailing side of Europa. We suggest that on Europa this spectral feature is caused by a sulphur atom-oxygen atom interaction within the water-ice lattice. It is not caused by an SO₂ surface frost, because the frost has a very different UV spectrum that does not match what has been observed⁷. Also, unlike Io, where a 4.08-μm absorption band assigned to SO₂ frost has been observed, no SO₂ IR band has been detected on Europa^{8.5} There is no evidence for a low-pressure SO₂ atmosphere, from either Voyager observations (A. L. Broadfoot, personal communication) or light curves of mutual satellite eclipses and occultations. If the imbedded sulphur atoms are sufficiently distant from each other in the ice lattice, they may acquire the bulk spectral character of a 'gas' in which the molecular interactions are small. This is the case for the present model. For the concentrations of sulphur detected, each deep-imbedded sulphur atom has between 120 and 200 Å³ of volume, at least an order of magnitude greater than the molecular volume found in a frost.

The possibility for the presence of the element sulphur is supported by other evidence. Data from the Voyager plasma experiment 10,11, and the low-energy charged particle (LECP) experiment¹², show that the galilean satellites are in an ion plasma composed primarily of sulphur and oxygen in which the co-rotating ions reach keV energies. The Voyager plasma experiment (J. Sullivan, personal communication) provided a measurement of about 7 sulphur ion cm⁻³ for the 'lower-energy' ions at Europa's orbit distance of 9.4 R_i. In this region their mean velocity is ~100-115 km s⁻¹. If we remove Europa's orbital velocity of ~ 13.7 km s⁻¹, then the mean flux of sulphur ions onto Europa's trailing side is $\sim 7 \times 10^7$ ion cm⁻² s⁻¹. Data from the LECP experiment indicate that there are also higherenergy sulphur and oxygen ions present, with energies in the hundreds of keV (ref. 12). An estimate of the integrated flux of these S and O ions is ~108 cm⁻² s⁻¹ with a mean energy of 100 keV (ref. 13, R. Johnson, personal communication). Thus, we can model the sulphur ion flux at Europa with two distinct distributions: a 1-keV source with a flux of $\sim 7 \times 10^7$ ion cm⁻² and a 100-keV source with a flux of $\sim 3 \times 10^7$ ion cm⁻² s⁻¹. Although laboratory data for heavy ion bombardment of water ice are meagre, R. Johnson and P. Haff (personal communications) have independently estimated that the low, 1-keV sulphur particles should penetrate the ice surface to a depth of \sim 35-40Å (about 10 molecular layers of water ice in the I hexagonal form). The 100-keV ion penetration is more difficult to estimate, but a linear model for depth versus energy seems reasonable until laboratory data are available. The faster ions may penetrate to between 3,000 and 4,000 Å.

In addition to deposition, the heavy ion impacts produce sputtering of the surface ice and over long periods of time there is erosion and the possibility for removal of a significant mass of water ice from Europa. Sputtering in water ice is anomalous when compared with processes for metals; there is an unexpectedly large yield of sputtered fragments from ice 14,15. The referenced studies showed that the sputtering yield is dependent on the mass of the ion as well as its energy. Johnson et al. 13 and Eviatar et al.16 have modelled the erosion at Europa caused by sulphur and oxygen ions diffusing outwards from Io's plasma torus. The erosion rates estimated are as high as 100 m of ice per 10° yr, which corresponds to 10° Å yr

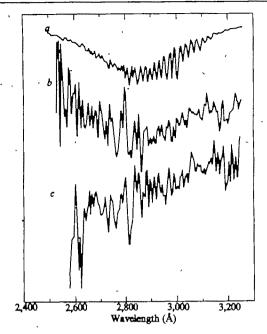

Fig. 1 a, The gas-phase absorption spectrum of the A-X band of SO_2 (ref. 6). The 10% attenuation illustrated in the depth of the band corresponds to a column density of 1×10^{17} molecules cm⁻². b, Three separate Europa trailing side and leading side spectra were added before the ratio spectrum was formed. Each separate trailing side spectrum shows ~3% absorption. Note that the brightness ratio of the two hemispheres is approximately constant at 2,600 and 3,200 Å. Thus, ratio spectrum is not seriously distorted. c, This trailing side/leading side ratio spectrum of Ganymede was formed the same way as the Europa ratio spectrum. The additional darkening of Ganymede's trailing side is seen in the gradual decrease of the ratio. No absorption minimum is detectable within the noise limit of the data. We conclude that this indicates on Europe the presence of S-O bands in a water-ice matrix, originating from sulphur ion implantation.

The ability to see sulphur deposition depends on the balance between injection/deposition and erosional loss to space or ballistic migration to the opposite side of Europa. The leading side of Europa has no detectable absorption band; the absorption would be marginally detectable, in our present limits, at a factor of about 4 less than what is present on the trailing side. Loss to space may be significant, but no atmosphere or strong outgasting signature was detected by either Voyager 1 or 2. The lack of a positive atmospheric detection by the Voyager UV spectrometer makes high erosion rates unlikely. Also, high erosion rates would reach the 3,000-4,000 A deep sulphur ions within days to months of their initial injection into the ice surface. Within that time ~1012-1014 new 'deep-seated' ions per cm⁻² would have been injected into the ice, and all the lowenergy ions lying in the upper 50 Å would have been removed. Even 10¹⁴ sulphur atoms (as SO₂) would not be detectable.

The depth of the Europa absorption band can be estimated from the individual spectra that make up the trailing side data set: ~3% attenuation within a factor of 2. To produce such an absorption, ~2×10¹⁶ molecules of SO₂ per cm² are required. Erosion rates of 104-106 Å yr-1 are about 2-4 orders of magnitude too large to retain sufficient sulphur atoms at a depth where an S-O molecular spectral band can be established and maintained. In fact, not all sulphur ions will make spectroscopically active bonds, so the inequality could be even larger. The fate of the lower-energy sulphur ions nearer the surface is unknown. They may be lost to space through energetic sputtering, or more probably, they co-deposit with any water molecules and oxygen atoms somewhere else on Europa after following ballistic trajectories from the sputtering site. Whether these sulphur atoms end up as sulphur dioxide molecules buried in a deposited

oxygenated water ice is also unknown. No laboratory data seem to be available for 2,800 Å light penetration into highly irregular water ice in which the many optical scattering centres far exceed the number of SO₂ molecules. If this ice deposit is relatively opaque, any real SO₂ could be hidden from detection. High erosion rates seem to be a problem for the detection of this absorption band. L. J. Lanzerotti has indicated that laboratory experimental studies seem to indicate that energetic particle bombardment of amorphous ice causes a conversion to a crystalline structure. We have assumed that the UV penetration into the surface ice is one or two wavelengths deep (3,000-5,000 A) because of the optical scattering centres and lattice defects. For an amorphous ice, this assumption should be adequate. Regular crystalline ice may permit UV penetration to 10,000 Å or more based on the fact that liquid water is quite transparent to 2,800 Å light. If the surface were crystalline ice, we would be seeing absorptions caused by the deepest implantations, and would bias our sulphur-ion source to a higher-energy distribution.

The lower rates of Johnson et al. 13 and the revised rates of Eviatar et al.16 seem more promising. At 103 Å yr-1, it would take 3-4 yr to reach the deeper-lying sulphur atoms in the damaged water-ice lattice. The equilibrium implanted sulphur concentration would be of the order of 3-4×10¹³ cm⁻², or only a factor of 5 less than what was detected. Johnson et al. 13 state that the rate could be as high as 100 m per 10° yr. If it were closer to 20 m, then an approximate equilibrium between deposition and erosion is possible. Even in this case, the fate of the low-energy, 1-keV sulphur ions that are stopped in the upper 40 Å is unclear. About 5×10^{14} sulphur ions cm⁻² should be an equilibrium value with an erosion rate of 20 m per 10° yr (0.2 yr to deplete), and this number is about 10 times smaller than the current limit of IUE detectivity. These sulphur atoms could be buried in waterice fragments that strongly scatter UV light and thus, not be detectable by UV absorption techniques.

We conclude that the IUE has detected an absorption band on the trailing side of Europa that resembles SO₂, and seems to result from S-O bond formation between deeply implanted sulphur atoms and the adjacent, damaged water-ice lattice. The sulphur detected seems to come from the energetic (hundreds of keV) sulphur ions that are present in the jovian magnetosphere. Given the current state of knowledge about the physical processes involved in heavy ion bombardment in water ice, we cannot be precise about the fate of much of the sulphur which undergoes sputtering along with the dominant water-ice fragments. An appropriate equilibrium condition can be found to match the observed spectral data if sputtering erosion occurs at no greater than 20 or so metres per 10° yr.

We thank the IUE observatory staff for support during the acquisition of these data, A.L.L. thanks R. Johnson, P. Haff, A. Eviatar and T. Johnson for helpful discussions, and L. J. Lanzerotti for a helpful review. This work represents one phase of research performed at the Jet Propulsion Laboratory, California Institute of Technology under NASA contract 7-100.

Vapour deposition polymerization of butadiyne

Arthur W. Snow

Chemistry Division, Naval Research Laboratory, Washington DC 20375, USA

In seeking preparative routes to highly conjugated polymeric systems, we have found that butadiyne, C₄H₂, the simplest diacetylene, may be polymerized from the vapour state by selective deposition onto an organic substrate polymer surface, such as polyethylene or Teflon. This polymerization is sensitive to the nature of the substrate surface, occurring most rapidly on a hydrocarbon surface. The polymer is characterized by IR spectroscopy as having a polyconjugated main chain with pendant acetylenic functional groups. ESR spectroscopy shows the polymer to be highly paramagnetic which is interpreted as indicating the presence of a large number of defects within the conjugated polymer. Structurally, this butadiyne polymer appears to be more closely related to substituted diacetylene polymers prepared by melt polymerization as opposed to those prepared by solid state polymerization.

In the solid state, mechanistic investigations with single crystal diacetylene polymerizations have elucidated monomer molecular and crystal structure requirements as well as a 1,4 polymer repeat unit structure¹⁻³:

$$nR - C \equiv C - C \equiv C - R \rightarrow C - C = C - C \Rightarrow_{n}$$
 (1)

In the melt^{4,5} or in solution^{5,6}, the polymerization is more complex, and polymer structures are less extensively characterized with combination of structures having been proposed^{4,5}:

$$R-C \equiv C-C \equiv C-R$$

$$R \qquad R \qquad R \qquad R \qquad R$$

$$\parallel \qquad \parallel \qquad \parallel \qquad \parallel \qquad \parallel$$

$$R \qquad R \qquad R \qquad R \qquad R \qquad R$$

$$R \qquad R \qquad R \qquad R \qquad R$$

$$R \qquad R \qquad R \qquad R \qquad R$$

The presence of the pendant group obscures much characterization information with regard to the polymer chain structure. The butadiyne (R=H) polymer, in addition to being conveniently prepared and handled as a vapour-deposited film, presents a unique opportunity for characterizing the chain structure.

Depending on the nature and composition of the substrate surface, these polymerizations may be conducted by thermal

initiation at temperatures ranging from 25 to 100 °C. Polymerization occurs most rapidly on a hydrocarbon surface but fluorocarbon surfaces can also be coated at reasonable rates. For example, in an atmosphere of 700 mm C₄H₂ at 25 °C, polyethylene film 3.7 thousandths of an inch thick, will increase its weight by 20% from polymer deposited over a 6-h period while a Teflon film 2.1 thousandths thick, subjected to a similar exposure for 36 h, increased its weight by 10%. Other surfaces such as quartz, glass, sodium chloride or aluminium oxide are highly inert showing only trace or no polymerization at all after a month's exposure to the same conditions. However, at 100 °C it is possible to deposit films on their surfaces. It is interesting that a simple hydrocarbon monomer should selectively polymerize on hydrocarbon or fluorocarbon surfaces. The polymer conforms well to the substrate surface, and, in the case of organic substrates, examination of a cut cross-section of the sample. some penetration of the substrate film the polybutadivne does occur. It is also noteworthy that the deposited polymer like the C₄H₂ monomer is a hydrocarbon, and, as might be anticipated, an accelerating polymerization rate is observed with a substrate such as Teflon. As might also be expected, the monomer will polymerize rapidly in the bulk liquid state. At high degrees of conversion this bulk liquid polymer has a brass-like metallic lustre similar to some substituted diacetylene single crystal polymers.

Characterization is made difficult by total insolubility in all organic solvents as well as concentrated sulphuric acid and 10% hydroxide. Consequently, it is necessary to use solid-state techniques.

In this polymerization system the growth of a very intense singlet ESR signal accompanies the polymerization of the liquid or gaseous monomer. The signal has a free electron g-value, a linewidth of $10 \, \mathrm{G}$ and a lorentzian line shape. Similar ESR spectra have been reported for solid state⁸⁻¹⁰, melt^{4.5} and solution^{6.7} polymerized substituted diacetylenes. However, the spin density of the melt polymerized diacetylene is significantly greater than that observed for solid state $(10^{19} \, \mathrm{spin}/g \, \mathrm{compared})$ with $10^{16} \, \mathrm{spin}/g$. A free electron ESR singlet is frequently observed in polyene systems and in usually ascribed to a defect in the conjugated polymer chain¹¹. The higher spin density may be correlated with a larger number of defects. Vapour deposited polybutadiyne has a spin density of $8 \times 10^{19} \, \mathrm{spin}/g$.

IR spectroscopy yields the most structural information. The collection of bands at 3,315, 2,090 and $640\,\mathrm{cm}^{-1}$ indicate the presence of a high concentration of pendant terminal acetylenic functional groups. The broad bands at 1,600, 1,210 and 885 cm⁻¹ suggest that the polymer chain is unsaturated and polydisperse. In the context of this polymerization, the band at 885 cm⁻¹ could be correlated with a central acene structure or, alternately, with the C-H vibrations of a 1,3,5-trisubstituted benzene structure¹². In describing the melt polymerized diphenyldiacetylene and dimethyldiacetylene systems, the former correlation in addition to other data has been used to propose a block polyene-polyacene copolymer structure composed of the products in equation (2). In the present case of unsubstituted butadiyne with direct detection of a high density of terminal acetylenic functional groups, a substituted polyphenyl is being considered as well.

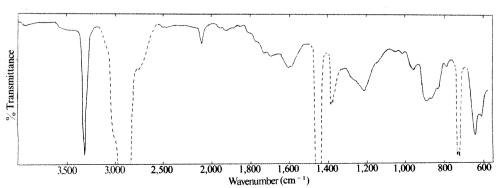

Fig. 1 Transmission IR spectrum of polybutadiyne deposited on a polyethylene film. The broken line corresponds to absorptions from the polyethylene.

The observation that the polybutadiyne penetrates into the substrate film suggests that absorbed monomer may diffuse through the surface before polymerizing. Polymer formation might be envisioned as involving formation of a substituted linear polyene structure followed by a partial intramolecular cyclization yielding structures represented in equation (2) or involving a trimerization of terminal acetylenic groups of two monomers and of a growing polymer molecule to produce a polymer with phenyl linkages in the main chain and pendent unreacted terminal acetylenic groups. The intense ESR signal suggests many defects exist in such a conjugated system. The kinetics, structure and properties of this deposition polymeric system are currently under study and will be reported elsewhere.

I thank the City University of New York, College of Staten Island for use of their ESR facility, and Professor N.-L. Yang for helpful discussions.

Negative exotic particles as low-temperature fusion catalysts and geochemical distribution

Christian K. Jørgensen

Département de Chimie Minérale, Analytique et Appliquée, University of Geneva, CH 1211 Geneva 4, Switzerland

Minute concentrations of unfamiliar particles (X+ or X-) with atomic weights M between 10^2 and 10^6 (10^{11} and 10^{15} eV) may be remnants¹⁻⁴ of the Big Bang or may originate in recent events (their expected properties are discussed elsewhere⁵). The adduct of X with a Z-nucleus acts as a superheavy isotope of (Z-1). It is shown here that although their geochemical separation would be less obvious than that of fractionally charged species containing unsaturated quarks^{6,7} it should still be possible to concentrate these exotic isotopes. Exceptional cases are the neutral adducts pX and ²DX, which may form tiny molecules with a second proton, or a polymer with a density $M \times 10^{10}$ g cm⁻³ which could act as a low-temperature fusion catalyst and explain the excess heat irradiated by Jupiter.

The fusion of four protons to 4He in most stars (including our Sun with a central temperature close to 15 × 10⁶ K) does not go⁴ mainly via the C-N-O catalysis proposed by Bethe, but rather takes place along a more direct path starting with two protons forming a deuteron, a positron and a neutrino^{8,9}. Zweig ted out that unusual quarks with charge (-4e/3) could bring together two deuterons, providing a one-stage fusion catalysis, if the quark has a much longer lifetime than the negative muon known11 to promote fusion in liquid hydrogen. If the stellar interior contains a small concentration of X which does not become inactivated by trapping on unreactive nuclei, the neutral pX starts by capturing a second proton to form a 'molecule' pXp+ having a wave function analogous to the hydride anion containing two electrons with a binding energy 1,836 times the electron affinity 0.75 eV of the hydrogen atom, not much above the prevailing kT. However, its ephemerial (but repeated) existence may help the otherwise low rate of forming 2DX and the two leptons. Although Coulomb barriers could be entirely avoided by subsequent reactions (pX+3He) or (2DX+2D) with increasing cross-sections at lower temperature due to longer DeBroglie wavelengths, the major problem in stellar interiors is the trapping of X on helium, carbon and so on. The nonrelativistic Schrödinger energy for the ground state of a system consisting of X and a nucleus with atomic weight A and charge Ze (where 1,823 is the reciprocal atomic weight of the electron)

$$-AZ^2 \cdot 1,823 \cdot 13.6 \text{ eV}$$
 (1)

almost independent of the atomic weight M of X^- (if $M \gg A$ the nucleus becomes the 'easily mobile' particle). For pX, equation (1) gives the binding energy as 25 keV, about 20 times $k\hat{T}$ at the solar centre, whereas ³HeX would have 300 keV and ¹²CX 10.8 MeV, although the spatial extension 6 of X^- and ^{12}C would decrease the latter value⁵. Exotic lithium may contain⁵ not only BeX but also BeX (where the X prevents the almost instantaneous fission in two α -particles) removing the bottleneck⁸ of nucleosynthesis.

Jupiter has an unaccounted heat production 12 slightly above 10²⁴ erg s⁻¹, which is of the same order of magnitude as the insolation (with an albedo 0.42). As the mass of Jupiter is 1.9×10^{30} g, this corresponds to an average energy production of 6×10^{-7} erg g⁻¹ s⁻¹ in comparison with 1.87 erg g⁻¹s⁻¹ for solar material. The temperature (128 K) doubles¹³ when looking down in the atmosphere through the 'window' at 2,000 cm where the IR lines are weak. If this excess heat production had continued at the present rate for 3×10^9 yr, then 10^{-8} of the Jupiter mass would have had to be transmuted from hydrogen to helium. A simpler alternative would be that the excess heat was due to the gravitational energy released by radial contraction. Indeed, the same amount of heat could be evolved by the radius decreasing ~400 km or 1%. But although such a contraction may seem insignificant, this slow re-adaptation of the radius causes several problems, one being that if there was a time when the temperature was double its present value, the radiative cooling would have been 16 times more rapid.

Although the rotational ground state of pX does not have an electric dipole moment (if X is a fermion, the hyperfine splitting between I = 0 and 1 may be several eV) it is important to know whether pX (having the average distance 3 bohr/ $2 \times 1,836 = 4.3 \times 10^{-12}$ cm) dimerizes, or polymerizes at room temperature to a highly compact liquid. The electrostatic dimerization energy of pX is ~10-15 keV. If droplets of such an exotic liquid exist (with a density close to M times 10¹⁰ g cm⁻³) they would form a general catalyst for nuclear reactions, and because of $M \gg 1$, they lose X by evaporation much less readily than protons. Such a material would be rather similar to a metal which has had its conduction electrons replaced by protons.

At first, one would expect irreversible trapping of X in CH₄, NH₃, and so on to create a worse problem in Jupiter than in the Sun, but the core of Jupiter is under such strong pressure that it may contain huge volumes of metallic hydrogen fairly separate from gaseous helium, and from the heavier elements, which may

not be soluble in metallic hydrogen. On the other hand, pX is expected to be soluble, and even effectively extracted. No fusion process is observed in hydrogen bubble chambers but all terrestrial hydrogen may have been stripped of X in early stages of the formation of Earth. An experiment at the Rutherford laboratory¹⁴ has put extremely low limits (10⁻²⁹-10⁻³⁰ X per proton if M is between 20 and 1,400). Direct mass spectrometric higher limits are close to 10^{-22} . Unfortunately, no comparable data have been presented for M between 104 and 106.

The relative concentration of exotic isotopes of a given element Z would be expected to be proportional to the ratio between the abundances of (Z+1) and of Z. Exotic boron, scandium, manganese and thallium would be good candidates from this point of view⁵. As boron isotopes ¹⁰B and ¹¹B can be separated on a commercial scale it might be useful to attempt to detect 12CX in the extreme fractions, although most boric acid has already been evaporated once from volcanoes. On the other hand, isotopes with A even as high as 106 should not be strongly fractionated in amorphous or crystalline solids by terrestrial gravitation, again except for polymeric pX. The latter should behave in a similar manner to that predicted 15 for high-M magnetic monopoles concentrating at the centre of the Earth. As technetium and promethium possess only β -unstable isotopes, it might be useful to look for them in minerals as adducts of X and ruthenium or samarium. In concentrated uranium minerals, spontaneous and neutron-induced fission maintain¹⁶ concentrations of 10^{-17} promethium and 10^{-12} (of the longer lived) technetium. The search has only 16.17 been for the specific isotope 147Pm but it would be interesting to know whether it is accompanied by comparable amounts of SmX.

Cahn and Glashow⁵ point out that the presence of X decreases the energy of α -decay to the extent that ²⁴⁴PuX and CmX may be long-lived on a geochemical time scale. Such exotic isotopes would show up as the (ultramicroscopic amount) neptunium and (as yet unreported) americium in minerals. These authors do not contemplate the capture of X by the heavy nuclei, which would be likely to induce fission, but consider the buildup of ⁸BeX (not representing a barrier to nucleosynthesis8 like the instantaneous decay of 8Be) by adding many consecutive 4He. Such a process may have occurred shortly after the Big Bang and give products normally only obtained⁸ in supernova explosions. One of the attractive candidates would be exotic actinium ²³²ThX. Because of radioactive equilibria, there are 10⁻¹⁵ actinium, 10⁻¹² protactinium (slightly below the concentration of ²²⁶Ra) to be compared with 12 p.p.m. of thorium, 16 p.p.m. of lead and 4 p.p.m. of uranium in the Earth's crust. If actinium is separated from a thorium mineral containing <0.3% uranium, the amount should be $<10^{-12}$ of the thorium. If a percentage of such a sample were 232 ThX rather than ²²⁷Ac, it would establish a concentration of 10⁻¹⁴ X⁻ per nucleus or $5 \times 10^{-17} \text{ X}^-$ per nucleon. The same argument would apply to a rare-earth mineral (containing <0.3% uranium) where exotic actinium may be more likely to be situated by the geochemical fractionation. These limits are far lower than the 10⁻¹⁰ first suggested and not much higher than the ratio between unsaturated quarks and nucleons, which is likely^{6,18} to have an order of magnitude of 10^{-20} (6,000 per g) if the existence of such species is not excluded by dogmatic quark confinement. It is possible that the very high atomic weights of exotic isotopes are concentrated on definite spots in large-scale mass spectrometers (like Oak Ridge calutrons) but there has been little effort to find them. A tandem accelerator 19 was recently used to detect oxygen isotopes with (not necessarily integral) atomic weights between 20 and 54, and upper limits for abundances 10⁻¹⁶-10⁻¹⁸ were found. However, the exotic ¹⁹FX discussed here would be heavier, and not particularly abundant8. A few atoms of ²³⁵UX may be detected by irradiating a photographic plate (or transparent plastic), having been exposed to the ultrahigh M-region of the mass spectrum of protactinium, with slow neutrons at high flux inducing fission. In such an experiment, the beam of Pa⁺ should be as free of neutral atoms (and molecules) as possible. The asymmetry of the short and intense track of the

fragment carrying X and the long track of the other, much more rapid, fragment should be conspicuous.

If positive X⁺ can be bound to nuclei (as predicted⁷ for positive quarks) by short-range interactions compensating for the electrostatic repulsion, separation of lithium would become of major interest as it would contain the adduct of ⁴He with X⁺; and the exceedingly low concentrations of polonium and of neptunium in minerals might contain the adducts of 209 Bi and 238 U with X^+ .

The two most promising concentration techniques seem to be ultracentrifugation and fractional distillation of liquid air. In aqueous, quite concentrated solutions, ultracentrifugation is an excellent way of separating proteins or synthetic polymer molecules according to molecular weight. Supposing kilogramme quantities of dissolved lithium chloride were suspected of containing traces of ⁸BeX or ⁹BeX, then by adding a separation buffer, such as gramme quantities of caesium chloride, any exotic lithium would show up in the almost vanishing, heavier fraction. On the other hand, if caesium nitrate is suspected of containing adducts of X^- with barium, $N(C_4H_9)_4^+NO_3^-$ or thallium nitrate may be used as separating agents.

The technology of separating the constituents of atmospheric air is highly developed. The boiling points of ³He and ⁴He are sufficiently different that 6LiX may boil at a higher temperature than neon. There is an enormous gap between the boiling point 27 K of the (18 p.p.m. of volume) neon and 77 K of the major constituent N2 without any known, or conceivable, minor constituent. Exotic neon ²³NaX would be situated in this gap. There is much less neon in our atmosphere than extrapolated from the cosmic abundance8 and a preliminary concentration by a factor of several thousand is obtained by the Earth having a gravitational field strong enough to retain exotic (but not conventional) neon over 109 yr.

Holt et al.20 wanted to investigate a possible superdense modification of nuclear matter by looking for the noble gas radon (of which the longest living isotope known ²²²Rn has the half-life 3.8 days) in xenon fractions from liquid air. Their negative result (with the higher limit 10^{-16} atom per xenon atom) is relevant to our problem. Because francium is even less abundant than radon, the search was really for exotic xenon formed by 133CsX, and caesium has a rather low cosmic abundance. Gaseous diffusion or centrifugation of krypton, which contains²¹ 0.01% CF₄, or collecting the almost absent fractions between krypton and xenon might enrich exotic krypton formed from the more abundant rubidium.

As pointed out by Fairbank⁶, exotic isotopes might be detected in dilute gaseous systems by the laser techniques developed22 for detecting single atoms. An especially clear case is the atomic spectrum of lithium, where the $2p \rightarrow 2s$ transition in the red has 0.2 cm^{-1} lower wavenumbers in ⁶Li than in ⁷Li. If this isotope shift is exclusively an effect of the electron moving the centre of gravity, it is 42 times smaller than the shift expected for any heavy isotope and the line positions then hardly depend on the explicit M value. Also exotic rubidium and caesium atoms should be quite good candidates for accurate monochromatic laser excitation but here the isotope shift is not due to a modified Rydberg constant. For our purposes, it is important that single xenon atoms23 have been detected.

I thank Professor Sheldon L. Glashow, for suggestions and fruitful discussions. I also thank him and Dr Robert N. Cahn for the important preprint (ref. 5), and Professor Renata Reisfeld for valuable discussions over indefinite continual stratification in matter.

²⁴¹Am from the decay of ²⁴¹Pu in the Irish Sea

J. P. Dav & J. E. Cross

Department of Chemistry, University of Manchester, Manchester M13 9PL, UK

Americium-241 is a long-lived α -emitting nuclide which has become one of the more important marine contaminants arising from the discharge of effluents to the Irish Sea from the nuclear fuel reprocessing plant at Windscale, Cumbria¹⁻³. These discharges contain ²⁴¹Am, currently $\sim 200 \text{ Ci yr}^{-1}$, and also the β -emitting nuclide, ²⁴¹Pu (half life 14.7 yr), which decays in the environment to ²⁴¹Am. Both americium and plutonium seem to be largely retained in sediments relatively close to Windscale 4-7 and a reservoir of 241 Am is building up both from direct deposition and from the radioactive decay of sedimented 241 Pu. Here we attempt to estimate quantitatively the size and rate of growth of this reservoir. Using data for Windscale discharges have estimated the probable sedimentary deposition of 241Am and 241Pu over the past 20 yr, and calculated the consequent additional ingrowth of 241 Am. The latter is now ~600 Ci yr rising towards a steady state ~1,300 Ci yr⁻¹ if present rates of discharge of 241 Pu are maintained. The present sedimentary reservoir of ²⁴¹Am is ~18,000 Ci, of which about 4,800 have resulted from 241 Pu decay in situ. Measurement of the 241 Pu/Puα isotope ratio in coastal sediments confirms our estimates of ²⁴¹Pu deposition. Outside the Irish Sea, in the dispersal plume into Scottish waters, we have concluded that the observed ²⁴¹Am concentration⁸ can be accounted for largely by ingrowth from the 241Pu transported in the water mass.

It has been established^{4.5}, by measurement of the activities of the α emitters ²³⁸Pu and ²³⁹⁺²⁴⁰Pu, in Irish Sea sediments, that >95% of the plutonium released from Windscale during the past 20-25 yr has collected relatively close to the point of discharge. In many locations, these sediments have remained largely undisturbed and the sedimentary record with respect to several isotopes, such as plutonium^{4,5,9}, caesium and other nuclides 10 can be related satisfactorily to the history of the Windscale discharges. Although levels of ²⁴¹Pu in sediments have not been measured systematically, the accumulation and subsequent decay of ²⁴¹Pu to ²⁴¹Am can readily be calculated if the quantities of ²⁴¹Pu initially deposited can be estimated.

It also seems likely that the marine discharges of ²⁴¹Am from Windscale will have largely accumulated in sediments in the region, although this possibility has not yet been established from measurement of activity levels in cores. The relative adsorption of ²⁴¹Am by suspended particulates in seawater in the Windscale area has been found^{6,7} to be greater than for ²³⁹Pu, and the settling out of such material would, therefore, be expected to remove americium more rapidly than plutonium. Consequently, almost the entire inventory of ²⁴¹Am, both discharged and ingrown, for the 20-25 yr of plant operation will probably be present in the sediments of the region. Interpretation of the sedimentary record for ²⁴¹Am can only be achieved if due allowance is made for ²⁴¹Pu deposition and decay.

Table 1 Marine discharges from Windscale and environmental accumulation of ²⁴¹Pu and consequent production of ²⁴¹Am

	Windscale	discharges (Ci yr ⁻¹)	Accumulated ²⁸¹ Pu (Ci)	Production of ²⁴¹ Am (Ci yr ⁻¹)
Year	Pu-α	²⁴¹ Pu	²⁴¹ Am	ner'	
1960	78	2,255		2,203	2
1961	104	3,012		5,044	6
1962	186	5,413	-	10,099	12

1979	1,335	40,383	212	361,579	560
1980				381,527	595

Pu- α includes ²³⁸⁺²³⁹⁺²⁴⁰Pu (refs 1, 2, 4). ²⁴¹Am data are not available before 1968, although discharges presumably occurred. ²⁴¹Pu data were not published before 1976; we have estimated these releases (shown in italics) from the Pu-α activities, using the mean 241 Pu/Pu- α isotope ratio (29.1) between 1976 and 1979. The environmental accumulation of 241 Pu, and consequent production of 241 Am, resulting from the Windscale discharges and corrected for radioactive decay were calculated by numerical approximation, using equations (1) and (2) and computed on a daily basis (assuming 1/365 of the annual discharge for each day). For calculation, the annual discharge of ²⁴¹Pu subsequent to 1979 has been taken as 37,469 Ci yr⁻¹, the average for the years 1976-79

The potential radiological importance of 241 Am, which reaches human consumption largely through fish and shellfish, became particularly apparent1 in about 1975-76, following several years of relatively large discharges of ²⁴¹Am from Windscale (Table 1). The relative contributions of discharged and ingrown 241Am to the environmental pool available to marine organisms has been examined¹¹, and the potential radiological significance of sediment held ²⁴¹Am is thought to be small^{11,12}. However, the conditions in which americium could be remobilized from sediments have not yet been fully investigated.

The ingrowth of 241 Am in sediments has been calculated from the estimated discharges of ²⁴¹Pu (Table 1), assuming total deposition of discharged plutonium. Plutonium-241 decays as follows:

241
Pu $\frac{^{6}}{^{14.7}yr}$ 241 Am $\frac{^{\alpha}}{^{433}yr}$ 237 Np $\frac{^{\alpha}}{^{-10^{6}yr}}$

The quantities of ²⁴¹Am formed and ²⁴¹Pu remaining, following the decay of a given initial quantity of 241Pu, are given by equations (1) and (2):

$$[^{241}\text{Am}]_{t} = [^{241}\text{Pu}]_{0} \frac{T_{\text{Pu}}}{(T_{\text{Am}} - T_{\text{Pu}})} \exp\left(-\frac{t \ln 2}{T_{\text{Am}}}\right) - \exp\left(-\frac{t \ln 2}{T_{\text{Pu}}}\right)$$
(1)

$$[^{241}Pu]_t = [^{241}Pu]_o \exp\left(-\frac{t \ln 2}{T_{Pu}}\right)$$
 (2)

where T_{Pu} and T_{Am} are the radioactive half lives of ²⁴¹Pu and ¹Am, respectively.

The sedimentary accumulation of ²⁴¹Pu by the end of each year, and the corresponding annual ingrowth of 241 Am, is given in Table 1. The rate of generation of 241Am has increased steadily, and by 1980 had reached a level ~600 Ci yr⁻¹. The continued discharge of ²⁴¹Pu at a constant annual rate would eventually give rise to a steady-state condition in the sediments in which the rates of deposition, and loss by radioactive decay, would have become equal. The steady state would be

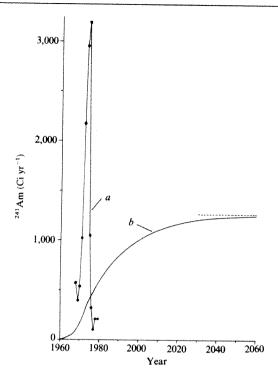

Fig. 1 Input of ²⁴¹Am to the environment. a, Direct discharge from Windscale; b, calculated production from radioactive decay of accumulated

241Pu in the environment from Windscale discharges.

approached exponentially (Fig. 1), with a half time of approach equal to the decay half life of ²⁴¹Pu. Assuming that discharges of ²⁴¹Pu remain at about their present levels, the ingrowth of ²⁴¹Am will level off at about ~1,300 Ci yr⁻¹. It is, of course, unlikely that discharges from Windscale will stay constant for this period in the future. However, the relative importance of the present rates of discharge of ²⁴¹Pu and ²⁴¹Am to future levels of ²⁴¹Am in the sedimentary environment is clear.

The sedimentary reservoir of ²⁴¹Am in the Irish Sea can be estimated if it is assumed (as seems likely) that effectively all the available americium, whether discharged from Windscale or ingrown, has been retained in the sediments. For the period 1960-80 we estimate that ~4,800 Ci of ²⁴¹Am will have ingrown from 241 Pu, whilst $\sim 13,000$ Ci has originated from direct deposition (this does not include any 241 Am discharged before 1968, for which we have no data, but it seems likely that the total released up to 1968 would have been relatively small, perhaps ~1,000 Ci). Correction for decay over this time period is insignificant, and the total reservoir is therefore ~18,000 Ci. To test these conclusions, we have measured the overall $^{241}\text{Pu/Pu-}\alpha$ isotope ratio in sediments taken from the Raven-

glass Estuary, adjacent to Windscale. Two cores, taken in 1978 to a depth sufficient to include the deposition for at least 20 yr, were homogenized and sub-samples analysed radiochemically. Plutonium was separated from the material by procedures ^{13,14} which exclude americium, and the activities of ²³⁸Pu, ²³⁹Pu and ²⁴¹Am determined by α spectrometry, both initially (²⁴¹Am = 0) and after about 14 months (Table 2). The measurement of ingrown ²⁴¹Am allowed the activity of the ²⁴¹Pu present in the original sample to be calculated15

The ²⁴¹Pu/Pu-α activity ratio (23.1) determined in these sediments is very close to that calculated (22.0) by summing the $Pu\text{-}\alpha$ and ^{241}Pu discharges (corrected for decay) up to the end of 1978. This value is significantly different from the current ratio at discharge, for which 241 Pu/Pu- $\alpha = 29.1$ (average, 1976–79). The close agreement between the measured and calculated values we take to confirm both that continuous accumulation of plutonium in sediments has occurred over that time, and also that our estimates of ²⁴¹Pu discharges for the years 1960-75 (Table 1) are essentially correct.

As an extension of these calculations, we have re-examined the data obtained by Murray et al.⁸ for the activities of ²⁴¹Am, ²³⁸Pu and ²³⁹⁺²⁴⁰Pu in Scottish coastal waters. It has been established ^{16,17}, largely from ¹³⁴Cs and ¹³⁷Cs measurements, that the main dispersal plume of radioactivity from the Irish Sea emerges northwards, passes along the west and north coasts of Scotland, and in part reaches the North Sea. The approximate average transit times for nuclides (1) to emerge from the North Channel of the Irish Sea¹⁶, and (2) to reach the sea area off the north-west corner of Scotland¹⁷ (Cape Wrath), following discharges from Windscale, are estimated at ~1.5 and 2 yr, respectively. The activity ratio, ²⁴¹Am/Pu-α, decreases from ~1.7 at discharge to ~0.06 in waters to the west and north of Scotland, as observed by Murray et al.8 who concluded that the Am and Pu- α are both of direct Windscale origin, the americium having been more rapidly removed from the water column. However, although qualitative reference was made^{8,17} to the possible contribution of ²⁴¹Am ingrown from ²⁴¹Pu, this was not estimated quantitatively.

We now suggest that these data, at least for the more northerly Scottish waters, can be interpreted on the hypothesis that the ²⁴¹Am arises almost entirely by ingrowth from ²⁴¹Pu during transport of the water mass. For the sea area to the north-west of Cape Wrath, the mean activities of ²⁴¹Am and ²³⁸⁺²³⁹⁺²⁴⁰Pu (Pu-α) from Murray et al.⁸ were 0.097 and 1.60 fCi l⁻¹, respectively. The inferred ²⁴¹Pu activity, ~44 fCi l⁻¹, would be sufficient to generate the observed ²⁴¹Am concentration over a period of ~1.4 yr. This is somewhat longer than the estimated transit time from the North Channel of the Irish Sea, but significantly less than the transit time from Windscale. If we assume that the ²⁴¹Am concentration results from an approximate steady-state condition, between rate of loss from the water mass (for example, by sedimentation) and rate of replacement by ingrowth, then the replacement time previously calculated (~1.4 yr) can be identified as the approximate mean residence time 18 for 241 Am in these waters. The probable existence of such a steady state is supported by the approximately constant value (between 0.05 and 0.08) for the ²⁴¹Am/Pu-α activity ratio round the Scottish coastline from the Minch to the North Sea8.

Although these conclusions are based primarily on the decay characteristics and observed activities in seawater of the plutonium and americium nuclides, the conclusions are not inconsistent with other facets of the marine behaviour of these elements, and may even help to remove an apparent anomaly. Thus, whilst most of the Windscale-discharged plutonium and americium seems to be rapidly removed to sediments, the remainder seems to be relatively well conserved in seawater, and to follow 137Cs in the dispersal plume. For plutonium, the probable explanation is that the sedimented and conserved fractions correspond to the element in the two different (environmentally stable) oxidation states, Pu(IV) and Pu(VI), respectively 19,20. For americium, the only plausible oxidation state in solution is Am(III), which is firmly and rapidly retained by sedimentary material within the Irish Sea^{6,7}. Thus, the

Table 2 Activities of ²³⁸Pu, ²³⁹Pu and ingrown ²⁴¹Am from sediment cores collected near Windscale at the end of 1978

Nuclide	Source activities (pCi)		
	Sample 1	Sample 2	
²³⁸ Pu	25.3	26.7	
²³⁹ Pu	102.2	107.7	
²⁴¹ Am	5.46	5.73	
²⁴¹ Pu	2,953	3,099	
Ratio ²⁴¹ Pu/Pu-α	23.2	23.1	

Activities were determined by a spectrometry 434 days after the preparation of Activities were determined by a spectrometry 4,34 days after the preparation of two sources from sediment cores collected from Ravenglass Estuary. The cores (~50 cm) correspond to a sedimentary deposition covering at least 20 yr, determined (J.E.C., unpublished) from the $^{134}\text{Cs}/^{137}\text{Cs}$ and $^{238}\text{Pu}/^{239}\text{Pu}$ isotope ratios^{4,9,10}. The ^{241}Pu activities were calculated¹⁵ from ingrown ^{241}Am . The measured activity ratio, $^{241}\text{Pu}/\text{Pu}-\alpha=23.1$, is very similar to that calculated by summation of the discharges up to 1978 (Table 1) that is $^{241}\text{Pu}/\text{Pu}-\alpha=22.04$. apparent maintenance of a rather constant Am/Pu ratio in Scottish waters is difficult to explain in chemical terms, as at first sight the phenomenon seems to imply a conserved fraction for americium, as well as for plutonium, in this water. However, we think a possible explanation, in terms of ingrowth from ²⁴¹Pu coupled with a rather short residence time for 241 Am in the water phase, is more plausible and is compatible both with the available environmental data and with the present understanding of the marine chemistry of americium.

Binary mixing in ocean-ridge spreading segments

M. F. J. Flower

Department of Geological Sciences, University of Illinois, Chicago, Illinois 60680, USA

Compositional mixing trends in eruptive mid-ocean ridge basalt (MORB) seem to be confined to short time-space intervals, possibly corresponding to single fracture-zone-bounded segments of a spreading ridge axis. Binary mixing is discernible from the variation in Ta, Hf, Rb, Sr and rare earth elements (REEs), and may be interpreted as reflecting dual mantle sources for locally-defined units of the axis or associated transform fracture zones. These sources reflect contrasting degrees and types of incompatible (or 'low- K_D ') element enrichment relative to a 'normal' MORB source characterized by uniform depletion in these elements. Enrichment in low- K_D elements, radiogenic isotopes and normative nepheline has long been recognized in some fracture zone magmas 1-4 and it is important to speculate on the possible influence of fracture zones on the chemical character of spreading axes. Consideration of chemical and isotopic variation at a single Atlantic spreading segment (36-37 °N) in a regional context suggests that transform fracture zones may be instrumental in both generating compositional heterogeneity in the mantle and permitting its expression in eruptive crust. It is proposed here that hybridization of 'enriched' fracture zone-derived melt and less-enriched or depleted rift-derived melt occurs in sub-axial magma supply systems during an active spreading phase.

Between the Azores Plateau (40 °N) and ~30 °N the Mid-Atlantic Ridge (MAR) is 'transitional' in type and characterized by short offset spreading segments forming a SSW-trending zone of accretion. FAMOUS and AMAR studies of the axial region at 36-37 °N (refs 5-7) documented geophysical and petrological properties of such segments (Rift Valleys (RV) 2 and 3) and DSDP Leg 378 studied their stratigraphic expression at four sites (332-335) perpendicular to the ridge axis. The sites represent a spreading flow line between 3.4 and 13 Myr BP. Most DSDP/IPOD basement sites reflect negligible sourcerelated chemical differences between stratigraphically contiguous lava series9. In contrast, the source-related chemical diversity at Site 332 and RV-2 (refs 10-12) is apparently characteristic of transitional ridge axes^{2,4}, and precludes common derivation for these series through processes of fractional crystallization in small reservoir systems 10-12.

While some interpretations of 36-37 °N have failed to emphasize the transitional character of the ridge axis, Schilling et al. 13 explained REE variation in this region in the context of spatial and temporal trends, postulating influx of an Azores plume or mantle 'blob' 14. However, the case for binary mixing of sources on the scale required by this model, at least in simple form, is not supported by regional isotope and low- K_D element variation for either secular (0-13 Myr) or isochronic (zero age) trends15. Other explanations for anomalous geochemistry in 36-37 °N magmas appealed to zoned and/or periodically refilled magma chambers 16,17, and also to the process of 'dynamic melting'10 which involves incremental melting and incomplete extraction of the melt phase as a typical feature of dilating partial melting environments. These concepts have been questioned18, and in the absence of seismic recognition and petrological evidence for sub-rift reservoirs 19-21 and the lack of chemical characteristics ascribed to dynamic melting at 'normal' ridge axes (for example, 22 °N), it is reasonable to explore alternative models.

Evidence from lava and xenolith variation at single (such as island) localities suggests that mantle heterogeneity is possibly vertical in nature^{4,22,23} thus coalescence of dilating and transform fractures could allow differential tapping of the mantle. Thermal models^{24,25} predict progressively shallower partial melting with increasing spreading rates. A simplistic but reasonable synthesis could postulate preferential zones of partial melting, activated by either normal rift dilation (high degrees of partial melting at shallow depth), or (depending on

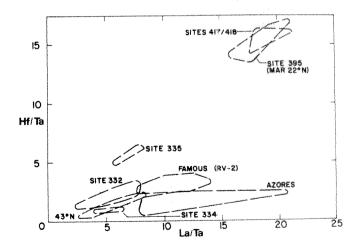

Fig. 1 Hf/Ta versus La/Ta diagram for basalts from the Atlantic/Azores region, data from refs 2, 8, 12, 36-39. Sites 395, 417 and 418 reflect 'normal' MORB depleted in low-KD elements. Note the absence of regional binary mixing; the colinear trend of FAMOUS RV-2 and Site 332; the lack of such a trend between 332, 334 and 335 (36-37 °N spreading flow line); and the diversity of 'enrichment' type compared with normal MORB.

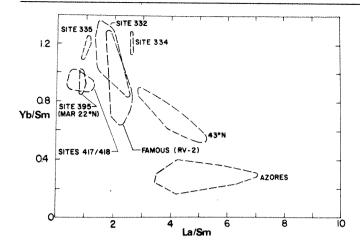

Fig. 2 Yb/Sm versus La/Sm diagram for basalts from the Atlantic/Azores region; data from same sources as for Fig. 1. Note the colinear RV-2-332 trend and lack of colinearity for 36-37 °N flow line; and the greater distinction of La/Sm (lower K_D) than Yb/Sm (higher K_D).

ridge axis kinematics) by transform fractures (low degrees of partial melting at greater depth), each environment constrained by a different range of pressure, temperature and hence, depth of melting. In turn, a given fracture zone-bound spreading segment might be characterized by (1) relative volumetric contributions from the two environments, and (2) the extent to which these hybridize during storage and/or transport to the surface.

Considering the range of variation at 36-37 °3N it seems that a combination of all factors is required. MgO-rich basalts are depleted in light REEs10 and there is a general correlation (not attributable to fractional crystallization) of low-K_D element enrichment, increases in La/Sm, Rb/Sr, Ta/La and so on and decreasing Mg/(Mg+Fe²⁺). This correlation may reflect the combined effects of source heterogeneity and fractional crystallization, and probably also variations in the extent of partial melting, and as a general effect may indicate relatively direct access to the surface from the rift-melting environment, but more lengthy transport/storage (hence fractionation) histories for enriched magmas derived from fracture zone melting, before hybridization. Most mixing models have considered ridgelongitudinal 'open' feeder systems²⁷ which are probably not typical for slow-spreading axes such as the MAR²¹. Possible roles for fracture zones have not been seriously examined. If transform fractures permit the confluence of different magma supply systems, the development of chemical gradients at midocean ridges may reflect the extent and nature of offset spreading as reflected by fracture zone frequency rather than regional mixing of different solid mantle fractions. This is apparent from recent data compilations²⁸ which show low-K_D element and radiogenic isotope peaks, together with lava temperature 'troughs', corresponding not only to positive gravity and thermal anomalies (proposed loci for mantle upwelling) but to major transform fractures. Mixing between fracture zone and rift systems is consistent with evidence for longitudinal magma flow at dilating ridges^{29,30} and with inferences from seismic and chemical data constraining magma systems to individual ridge segments 11,19,20

Low- K_D element ratio-ratio plots are a useful way to study source-characteristic mixing. If each ratio denominator is identical (for example, K/Rb and Sr/Rb) mixing produces straight line variation between the two³¹. Data for DSDP Sites 332 (3.4 Myr), 334 (10 Myr) and 335 (13 Myr), FAMOUS RV-2, the Azores and other Atlantic localities are depicted in two low- K_D element ratio diagrams: Hf/Ta-La/Ta and Yb/Sm-La/Sm (Figs 1 and 2). Hf/Ta-La/Ta plots for RV-2 and 332 reflect significant variation in source composition, distinct from that of 'normal' ridge segments (represented by Sites 395, 417

and 418) and consistent with binary mixing. The variation is also distinct from that of older sites at 36–37 °N and from other 'enriched' localities in the Atlantic. A similar, more diffuse, relationship is observed for Yb/Sm-La/Sm variation (Fig. 2). In general, variation for given localities such as spreading segments or individual islands is consistent with simple binary mixing, whereas variation on a regional scale reflects a complex array of fractionation processes in the mantle. The relation to small-scale rather than large-scale tectonic features is probably highly significant, and bears on fundamental problems concerning the chronology and origins of mantle heterogeneity.

 87 Sr/ 86 Sr and 143 Nd/ 144 Nd ratios for FAMOUS RV-2 lavas 18 indicate isotopic homogeneity for the source region at present. and, as for many low- K_D element-enriched magmas, reflect a time-integrated source depletion in Rb and LREE compared with chrondrites 18,32. White 18 suggests that this reflects that either Rb/Sr and Nd/Sm ratios in the source are uniform, or that heterogeneities in these ratios are young (≤80 Myr). Although White prefers the former interpretation, his data reflect Rb/Sr and Nd/Sm variation between 0.024-0.063 and 0.267-0.337 respectively (Fig. 3) and show a strong negative correlation. This clearly favours the interpretation that heterogeneity is of recent origin. The approximate coincidence of RV-2 and Site 332 Rb/Sr-Nd/Sm variation to bulk Earth estimates in Fig. 3 is probably fortuitous in view of the depletion history recorded by Sr and Nd isotopes. Together, the low-KD and isotope components suggest that generation of heterogeneity expressed in the 36-37 °3N lavas is coeval with, and may be complementary to, processes of magma generation as determined by the overall tectonic environment. From geophysical considerations³³ local binary mixing of mantle fractions is unlikely, suggesting that mixing of different mantle-derived magmas is a more plausible mechanism for producing mantle-related mixing trends of the type observed. The fracture zone-rift explanation for binary mixing is also appealing for its ability to explain the origins of low- K_D element enrichment in the mantle. Enrichment by metasomatic veining of fertile peridotite has been documented in terms of mineralogy, chemistry and isotopic equilibration^{34,35} and may be the result of incipient melting in garnet lherzolite. The thermal-kinematic nature of transform fractures and the correspondence of magmatic enrichment/mixing trends to local rather than regional tectonic features suggests that transform fracturing may actually provoke

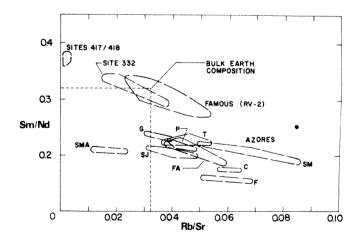

Fig. 3 Sm/Nd versus Rb/Sr diagram for basalts from the Atlantic/Azores region: data from refs 8, 10, 12, 18, 36-39. SMA, Santa Maria; G. Graciosa; T, Terceira; P, Pico; SJ, Sao Jorge; FA, Faial; C, Corvo; F. Flores and SM, Sao Miguel. Note the apparent correspondence of RV-2 and 332 to 'bulk Earth' composition (in contrast to Sr and Nd isotope compositions (ref. 18), 'depletion' of 'normal' MORB in Nd and Rb, and 'enrichment' of Azores in Rb (except Santa Maria) and Nd.

generation of low-percentage melt increments at depth, and provide upward access for these into depleted 'normal' mantle to form secondary 'enriched' sources for ridge axis magma. In this context, the evaluation of small variations in pressure, temperature, percent melting and disequilibrium in determining the nature of enrichment becomes critical in explaining the unique chemistries of enriched-magma associations.

I thank Paul Robinson, Hubert Staudigel and Alan Zindler for helpful discussions.

Sanidine spherules at the Cretaceous-Tertiary boundary indicate a large impact event

J. Smit & G. Klaver

Geological Institute, Nieuwe Prinsengracht 130, Amsterdam, The Netherlands

The hypothesis that a catastrophic impact of an extraterrestrial body caused the terminal Cretaceous mass extinctions of dinosaurs, planktonic foraminfera and other species is now accepted as respectable following the discovery of a worldwide iridium enrichment in the Cretaceous-Tertiary (K-T) boundary clay¹⁻⁵. In the basal lamina of the K-T boundary clay of Caravaca (Spain)⁷ numerous spherules were discovered composed of finely crystallized, almost pure K-feldspar in the structural state of high sanidine. It is concluded here that these spherules solidified from a melt and were probably derived from the impacting body. This poses problems as high K-values are not reported from bulk analyses of meteorites⁶. The K-feldspar phenocrysts reported in some iron meteorites²³ suggest the body may have been a metal-sulphide-silicate planetesimal. A cometary body is suggested as an alternative.

The strongest geochemical extraterrestrial signals have been recorded in the basal lamina of the 10-cm thick K-T boundary clay of both the Barranco del Gredero section (Caravaca) and the 'Fish-clay' at Stevns Klint (Denmark)1-5. These basal millimetres show the highest concentrations of the siderophile elements Ir (44 and 86.7 parts per 109 respectively), Os, Cr, Co and Ni, and also a significant rare earth element (REE) depletion. (J.S and Ten Kate, in preparation). The REE depletion, if caused by the low concentration of REE in the impacting body, suggests a large meteoritic contribution in the basal lamina, regarded as 'fall-out' level of the impact event. Moreover, anomalously high amounts of the chalcophile elements Zn, As, Se, and Sb have been found, elements which are not present in high concentrations in known extraternestrial material⁶. The sanidine spherules occur as small (0.5-1 mm) globules, dumbbells and disks only in the 'fall-out' level of the K-T boundary clay at Caravaca; some 50-300 per cm3 sediment were found. X-ray diffraction analysis of the spherules has been carried out on a Guinier camera, using CuKα radiation and corundum as internal standard. The diffraction pattern shows only K-feldspar lines of good quality, which permit accurate determination of the 2θ angles ($\overline{2}04$; 50.78°, 060; 41.59°, $\overline{2}01$; 20.98° (± 0.1 °)) and lattice constants (Table 1, Fig. 1). Indexing of the Guinier pattern according to Borg and Smith8 as sanidine is unam-

Furthermore, the spherules were analysed chemically by electron microprobe and instrumental neutron activation analysis (INAA) (Table 1) and have been examined by scanning electron microscope and petrographic microscope (Figs 2, 3).

In good agreement with the X-ray diffraction, the microprobe analysis gives a K-feldspar composition of the formula $K_{0.95}Na_{0.01}Fe_{0.01}Al_{0.98}Si_{3.01}O_8$. The high K/Na ratio is remarkable: K/(K+Na) = 0.99. No difference in chemical composition has been observed between the centre and the edge of the spherules. Within the spherules occur numerous small opaque inclusions. Analysis of two of these inclusions (Table 1) shows a high Cr and Ni (9,400 p.p.m.) content, considerably more than the clay in which the spherules were found. As iridium generally correlates positively (above zero in impact melts) with Ni (refs 9, 10) we expect the inclusions to have a high Ir content. The whole rock INAA analysis of the spherules confirms the high K/Na ratio. Co, Cr, Ni, As and Sb occur in high concentrations and are presumably concentrated in the opaque inclusions. REE values are low. Similar low values in K-feldspar are rarely reported11

A preliminary K/Ar dating (E. A. Hebeda, personal communication) on handpicked and ultrasonically cleaned, but

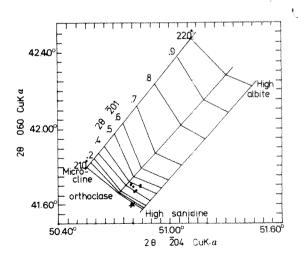

Fig. 1 Plot of 2θ angles ($\overline{2}04$) and (060) on Wright's ¹⁹ structural state diagram of the spherules (+) and reported ^{16,17} authigenic sanidine (lacktriangle). The 2θ angle (201) of the sanidine spherule predicted from this diagram (20.9°) hardly differs from the measured 2θ $(\overline{2}01)$: (20.98°) . Authigenic sanidine shows 2θ $(\overline{2}01)$ of 20.95° -21.01°, well outside the predicted range of 21.3°-21.42°. ×, Sanidine phenocrysts in Colomera iron-meteorite 23.

Fig. 2 Thin sections of the sanidine spherules from the Cretaceous-Tertiary boundary, showing dendritic microstructure and fibres radiating from the surface and from opaque inclusions. Scale bar, $75~\mu m$.

otherwise untreated sanidine spherules, gave a minimum age of 44 ± 2 Myr. This is ~ 21 Myr less than the generally accepted age of 65 Myr for the K-T boundary¹², and is probably due to loss of argon or to impurities within the spherules.

Figures 2 and 3 show the microstructure and crystal structure of the spherules. The microstructure consists of minuscule dendrites and fan-shaped fibres, radiating from the surface into the spherule, and from the opaque inclusions, acting as nuclei (Fig. 2a-c). This texture suggests that crystallization took place rapidly¹³.

But how did the spherules originate? Authigenic growth of K-feldspar as microcline or adularia occurs commonly^{14,15}, but little information on authigenic sanidine is available^{16–18}. Authigenic growth of the spherules, however, is considered unlikely, because of the crystal shape, texture and structural state of the sanidine.

Authigenic crystallization takes place slowly, which usually leads to equidimensional, euhedral crystals, in strong contrast with the texture shown in Figs 2 and 3. Figure 1 shows the difference in structural state¹⁹ between the sanidine of the spherules and authigenic sanidine—authigenic sanidine is clearly anomalous. The only argument for authigenic growth would be the high K/Na ratio, because of the limited miscibility of K- and Na-feldspar at low temperatures¹⁵.

A volcanic origin for the spherules is also considered unlikely, because of the lack of other volcanic products at the K-T boundary, and the high K/Na ratio.

A relation with the terminal Cretaceous impact event remains the most plausible explanation. We may consider the spherules either as microtektites, which implies a terrestrial source rock, or as ablation products of the incoming projectile(s). Mikrotektites are normally glassy objects with a terrestrial chemical composition, ejected from an impact crater²⁰.

The initiation of crystallization at the surface of the spherules indicates that the spherules were already in their present, spherical shape when crystallization started. This favours strongly rapid cooling, beginning at the surface of a molten silicate droplet. Perhaps the 'monomineralic' composition of the melt of the spherules has led to dendritic crystallization, instead of glass. For microtektites the high K/Na ratio would be difficult to explain, although K enhancements in crater ejecta and impact melts have been observed²¹.

The texture of the spherules resembles the texture of chondritic ablation spherules reported by Blanchard et al.²², although the chemistry of present spherules is completely different. Ablation products, rich in K are not yet reported; K is an accessory element in all types of meteorites (150–1,400 p.p.m., ref. 6), and only from a few iron meteorites are K-feldspar phenocrysts reported²³ with the same X-ray pattern as the spherules (Fig. 1). The enriched chalcophile elements As, Se and Sb may be derived from a comet, which is supposed to have preserved (part of) its volatile constituents. K may similarly be

derived from a comet. However, K-feldspar is a differentiated mineral, which probably does not occur in undifferentiated Solar System material, as comets are supposed to. Bandhari and Shah's report²⁴ of K-rich globules from Luna-20 soil is notable as the soil of the Moon is supposed to contain meteoritic and cometary material (J. Hertogen, personal communication). A third possibility is that the KAlSi₃O₈ spherules are condensates of more volatile constituents, which are vaporized on entry to the atmosphere or on impact on the Earth.

We suggest that sanidine spherules, restricted to the 'fall-out' lamina of the terminal Cretaceous impact event, are derived from a projectile, rich in chalcophile and moderately volatile elements like K, As, Se, Sb and Zn. Further chemical analysis of the spherules and their inclusions may shed light on the terminal Cretaceous impact event and on the composition of the impacting body.

We thank J. J. Hermes, J. E. van Hinte, E. A. Hebeda, S. Pen, M. de Bruin and many others for their contributions. The ZWO-WACOM Electronmicroprobe Laboratory at the Free University and the Interuniversity Reactor Institute were used for chemical analyses.

Lamellar-zonal bone with zones and annuli in the pelvis of a sauropod dinosaur

R. E. H. Reid

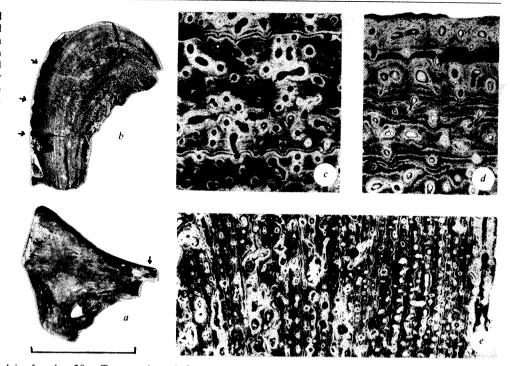

Department of Geology, The Queen's University of Belfast, Belfast BT7 1NN, UK

De Ricqlès¹⁻⁷ distinguishes two principal types of primary (unremodelled) compact bone (compacta), which he terms lamellar-zonal and fibro-lamellar. In the former, bone laid down by accretion at the periosteal (external) surface shows a general coarsely lamellated texture, and vascular canals (for blood vessels) are often sparsely developed and sometimes lacking. Primary osteons, formed by inward growth of bone inside vascular canals, may be present or absent. This type of compacta is seen in bones which grow slowly or only to small sizes, and is the only type seen in most ectotherms. In contrast, fibrolamellar bone is always rich in primary osteons, set in a matrix of woven bone which is typically laid down rapidly. This type of bone is seen mainly in medium- to large-sized endotherms, and reflects their ability to reach such sizes more quickly than comparable ectotherms. In ectotherms, lamellar-zonal bone may show a cyclical alternation of thin layers of dense bone. termed annuli, with thicker vascular layers known as zones, but it is claimed2 that such features are not developed cyclically in endotherms. The presence of fibro-lamellar compacta, without annuli and zones, in various dinosaurs is hence seen as evidence that dinosaurs were endotherms. However, I report here a case in which compact bone from the pelvis of a dinosaur is instead lamellar-zonal, and shows typical zones and annuli.

The material studied consists of the proximal parts of an incomplete left pubis (Fig. 1a) and ischium (anterior and posterior bones of the lower part of the pelvis) from an undescribed sauropod dinosaur, found in the Northampton Sands Formation (Middle Jurassic, Lower Bajocian) at Harlestone, near Northampton, UK. Both bones are broken across their shafts, and the compacta seen in section at the broken ends shows conspicuous concentric annulations (see Fig. 1b), which are due to its formation from a series of circumferential increments. The external surface shows fine longitudinal grooving, and the vascular canals exposed at broken surfaces are predominantly longitudinal. The compacta surrounds a core of spongy bone (spongiosa), containing tubular cavities which again run longitudinally.

In the pubis, the compacta is thickest on the outward-facing surface, and most of the increments are several times thicker on this side than on the inward side. Each increment is underlain by a sharply defined surface, which resembles the external surface. Where these increments are thickest (Fig. 1c), each one typically begins with a thin (for example, 25 µm thick) but well defined layer of bone, in which vascular canals occur mainly over

Fig. 1 Left pubis of a sauropod dinosaur (British Museum (Natural History) exhibit no. R. 9472) from the Northampton Sands Formation near Northampton, UK. a, Proximal part of the pubis, inner face, to show the dinosaurian character of the specimen and the source of the sectional material (arrowed), scale 30 cm. b, Polished section at the point arrowed in a, viewed distally, showing the annulated appearance; arrows mark the positions of traverse lines used in measuring from a parallel thin section (see text and below) \times_{4}^{3} . c, One increment of the primary compacta and parts of two others, as seen where the increments are thickest (b, left-hand side). showing two of the thin basal annuli and one complete vascular zone, ×30. Moving inwards, the outermost 11 such increments have average thicknesses (three measurements) of 0.30, 0.34, 1.06, 1.17, 0.47, 1.04, 2.27, 2.15, 1.14, 1.78 and 1.78 mm. respectively. d, The outermost three increments of the compacta as seen where the increments are thinnest (b,

right-hand side), and part of the underlying fourth, $\times 38$. e, Traverse through the compacta where its increments are thinnest, from the external surface (at right) to near the limit of the spongiosa (left), $\times 12$.

grooves in the underlying surface. A second similar layer sometimes follows, usually less distinct. The rest of the increment is formed by strongly vascular bone, showing little or no concentric layering, but packed with primary osteons. The vascular canals of this part of the increment are irregularly interconnected at rather wide intervals, and show no regular arrangement. The increment then ends with a surface which resembles the one underlying it. Up to 13 such increments were counted in a section cut parallel to the surface shown in Fig. 1b, with an average thickness (three measurements) of 1.23 mm in the outermost 11 (range 0.30-2.27 mm; see Fig. 1 legend). Where the increments are thinnest (Fig. 1d,e), there are usually several thin basal layers, but the vascular parts are reduced, and their vascular networks may be single layered. Bone under the terminal surface may also show a layered appearance, and this extends through the whole depth of some increments. Up to 17 such increments were counted, with an average thickness of 0.35 mm. Intervening parts of the compacta show conditions intermediate between these two types (Fig. 1c,d).

A sample from the ischium shows compact of the type seen in Fig. 1c, but only five or six increments remain between the surface and the spongiosa. (As usual, the spongiosa grew outwards by encroaching on the compacta from within, and these different counts of increments reflect different degrees of encroachment.) In both bones, Haversian systems (secondary osteons, formed from bone laid down in vascular canals cut though the primary structure by resorption) are mainly seen near the spongiosa. The bones are iron stained, with their fine structure partly masked as a result. Using cross-polarization, the fine banding of lamellar bone can be found in primary osteons, and in the Haversian bone and spongiosa, but it is not seen in the thin circumferential layers which seem to consist of parallel-fibred bone. Woven bone can be recognized in parts, between primary osteons.

Although these bones are pelvic, their shafts can be compared with those of limb bones, and the concentric structures seen in their compacta reflect the way in which new bone was added at the surface. These structures are not a result of internal remodelling, which is limited to replacement of the primary compacta by Haversian bone and spongiosa. The surfaces between successive increments mark pauses in growth represented by a resting line at the base of each increment as seen in section (see Fig. 1c). Each increment, as developed in

Fig. 1c, can be interpreted as consisting of a thin basal annulus with a vascular zone outside it; the modified pattern seen in Fig. 1d shows the condensing effect of slower growth. These features are repeated cyclically through the whole depth of the primary compacta, up to 17 times down to the level of internal replacement by spongiosa. There is no sign that this growth plan replaced an earlier non-cyclic pattern. Hence, they cannot be dismissed as a result of incidental formation of annuli, or their formation at the end of normal growth (compare ref. 2, p. 109 and ref. 4, p. 53). Annuli are more usually found under resting lines3, but annuli which follow resting lines, as in the material examined here, are known from the pelycosaur Dimetrodon, for example (Fig. 4 of ref. 8). The most similar material observed by de Ricqlès (Fig. 3 of pl. 19, ref. 6) is compacta from limb bones of the fossil amphibian Stenotosaurus (Subclass Labyrinthodontia, Order Temnospondyli, Suborder Stereospondyli, Lower Triassic), which may show thick vascular zones packed with primary osteons as found in parts of the material examined here (Fig. 1c), or a more condensed pattern (Fig. 9 of pl. 5, ref. 2) like that shown here in Fig. 1d,e. The compacta from Stenotosaurus was specifically shown^{2,6} as being lamellar-zonal bone with zones and annuli; therefore I take this to be the character of the compacta of the bones studied here.

The primary compacta of this sauropod pubis and ischium is thus not of the fibro-lamellar type, thought⁷ to be general in dinosaurs, and shows features (cyclically repeated annuli and zones) described^{2,4,6} as characteristic of ectotherms and absent² from known endotherms and dinosaurs. Their presence here cannot be dismissed as due simply to slow growth of the pelvic bones (compare p. 139, ref. 7), because the presence of resting lines between thick vascular zones implies that periods in which no bone was deposited periosteally occurred alternately with periods of more or less rapid growth. Where the zones are thick (Fig. 1c), they are more vascular than is usual in modern reptiles (compare with ref. 9), but can be closely matched in the amphibian Stenotosaurus, which is not a likely endotherm (all modern amphibians are ectothermic)—this condition has also been interpreted² as being related to aquatic modes of life. Thus the sauropod discussed here seems to have been ectothermic, unless annuli and zones can be cyclically developed in an endotherm. At first sight, this result is surprising but de Ricqlès' main work 8.10-13 on bone in fossil amphibians and reptiles contains no systematic study of dinosaurs, and his summary⁷ of their bone

histology makes use of work by other authors. Some material in the theropod Allosaurus is thought to show lamellar-zonal example if bone included by Seitz (Figs 53, 54 of ref. 14) from the theropod Allosaurus is thought to show lamella-zonal structure. This suggests that the material examined here only seems to be anomalous because no adequate systematic study of dinosaurian bone histology has yet been published.

I thank Drs H. W. Ball and A. J. Charig for permission to study the material, and Dr Charig for identification; Dr A. C. Milner and Mr C. A. Walker for assistance; Professor T. J. Harrison and Dr M. Ferguson for discussion; and The Queen's University of Belfast for travel grants. The sections were cut by Mr W. G. Allingham and Mr S. Watters processed the photographs.

New subclass of birds from the Cretaceous of South America

C. A. Walker

Department of Palaeontology, British Museum (Natural History), Cromwell Rd, London SW7 5BD, UK

Current classification of birds recognizes three subclasses which morphologically distinct: the Archaeornithes for Archaeopteryx, the Odontornithes for the Hesperornithiformes and the Ichthyornithiformes, and the Neornithes for all modern birds and their extinct immediate relatives. (Some authorities1 prefer different names for some of these taxa.) I have examined new material recently discovered in the Upper Cretaceous rocks of Argentina which indicates the existence of a group of birds having features so different from those of the currently recognized subclasses that they seem to represent a fourth subclass, here named the Enantiornithes ('opposite birds'). I describe unique features of the Enantiornithes which include a reduced outer metatarsal, in some forms an extreme modification of the remaining elements of the tarsometatarsus, a highly modified pectoral girdle, and sometimes a characteristic perforation in the proximal end of the humerus.

In the 1970s Dr Jose Bonaparte (Museo Argentino de Ciencias Naturales, Buenos Aires) conducted field excavations in the continental deposits of the Lecho Formation (Salta Group) of El Brete (Salta Province), northwestern Argentina, the age of which is probably Maestrichian (uppermost Cretaceous). The collection included ~60 individual bones, some associated, which are presumed to be avian; they show no similarity to any of the accompanying dinosaur remains (a titanosaurid, a coelurosaur and a carnosaur)2. This bird material consists of all the major postcranial elements and the posterior portion of a left lower jaw ramus; it will be housed in the Universidad Nacional de Tucumán, Argentina. I have described the material here as belonging to members of a single monophyletic group. Although

found separately, most of the elements are of a single unique form: for example, there are five coracoids, all very different from those of other birds, including that of Archaeopteryx. The same is true of the 10 humeri, 6 ulnae, 5 femora, 5 tibiotarsi and 5 tarsometatarsi. The hypothesis that all these remains belong to one group is supported by the fact that there is some degree of association between the elements: for example, one articulated group consists of scapula, coracoid and humerus, and in another case a very similar humerus was found with the whole of the rest of the forelimb skeleton. The fore- and hindlimb elements can be associated only tentatively, by size, and by a single associated ulna and tibia (4032).

However, within the highly characteristic structure, both size and shape vary considerably. The material falls into five categories, of which three have about the same dimensions (but differ from each other in form); in the other two categories the material is much smaller and much larger respectively. The morphological differences between the five tarsometatarsi are particularly striking; they clearly represent three lines of evolution so distinct that, had they still been extant, each would probably have been assigned a separate ordinal status. The differences between the humeri are less marked but are nevertheless significant.

The new specimens from Argentina possess certain characters common to all birds. These include a strap-shaped scapula; a coracoidal foramen (=supracoracoidal foramen of Ostrom3); a humerus with proximal and distal expansions almost in the same plane, well developed deltoid and bicipital crests, a pneumatic fossa and/or foramen and a well marked ligamental furrow; a radius with an expanded distal end; an opisthopubic pelvis; a pit in the head of the femur for the attachment of the round ligament; and some degree of fusion of the metatarsals.

A cladistic analysis of the remaining characters of this group, for which the new name Enantiornithes ('opposite birds') is proposed, results in the cladogram shown in Fig. 1. Table 1 lists the synapomorphies common to Enantiornithes and all other post-Jurassic birds (Odontornithes and Neornithes) in which they differ from the corresponding character-states of Archaeopteryx, while Table 2 lists the synapomorphies which are shared by the Odontornithes and Neornithes, in which they differ from the corresponding character-states of the Enantiornithes.

The positive character-states unique to the Enantiornithes (nos 3-6a, 8, 10 and 13 in Table 2) make it impossible to place them in any of the three major groups already recognized (Archaeornithes, Odontornithes and Neornithes). There are, however, plesiomorphic similarities with Archaeopteryx, including the length and slenderness of the femur and the imperfect fusion of the tarsometatarsus. As I do not support strictly Hennigian classifications I suggest that this group be assigned the status of a subclass, thus fitting it into the traditional classification as coordinate with the other three subclasses.

The coracoid (Fig. 2a, D and E) differs from those of typical birds, not only in having no procoracoid but also in its lack of a prominent sterno-coracoidal process. Perhaps the most fundamental and characteristic difference between the Enantiornithes and all other birds is in the nature of the articulation between the scapula (Fig. 2a, C) and the coracoid, where the 'normal' configuration is completely reversed. The humerus too possesses unique features: for example, the head is almost flat in anconal view (Fig. 2a, B) while there is a well marked depression

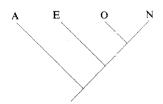

Fig. 1 Suggested cladogram for the class Aves. A, Archaeornithes; E, Enantiornithes; O, Odontornithes; N, Neornithes.

Table 1 List of the synapomorphies shared by the Enantiornithes and all other post-Jurassic birds, in which they differ from the corresponding character-states of Archaeopteryx

			•
	Character	Archaeornithes	Enantiornithes, Odontornithes and Neornithes
1	Vertebral centra	Not saddle-shaped	Saddle-shaped (? cervicals only in Enantiornithes)
2	Number of sacral vertebrae	Probably 6	At least 9
3	Caudal vertebrae	Not reduced	Reduced to a pygostyle (indication only in Enanti- ornithes)
4	Sternum	Not developed	Well-developed, with keel
5	Abdominal ribs	Present	Absent
6	Coracoid	Lunate	
7	Proximal carpals	Radiale and ulnare of simple shape	Elongate, spatulate at sternal end
8	Distal carpals	Lunate bone only	Scapholunar and cuneiform of complex shape Trochlea carpalis and extensor process fused together to form part of carpometacarpus, with
9	Metacarpals	Unfused II-IV (I-III)	pollical facet and well-developed metacarpal facet Fused
10	Ilium and ischium	Not fused distally	
11	Degree of fusion of astragalus and calcaneum to tibia	Nil or only partial (ref. 5)	Usually fused to enclose ilio-ischiadic fenestra Complete

Table 2 List of the synapomorphies shared by the Odontornithes and the Neornithes, in which they differ from the corresponding character-states of the Enantiornithes

	Character	Enantiornithes	Odontornithes and Neornithes
1	Saddle-shaped vertebral centra	Probably in cervicals only	In most cases, in cervicals and dorsals
2	Procoracoid	Absent	Present
3	Scapular articulation on coracoid	Boss	Facet
4	Coracoid articulation on scapula	Facet	Boss
5	Head of humerus	Flattened profile	Rounded profile, no flattening
6	Palmar surface of humerus:	F	Rounded prome, no nattening
	a, depression below head	Well marked	Absent
	b, brachial depression above	Absent	Well developed, surrounded by scar of brachialis
	distal end		anticus muscle
7	Internal condyle of humerus	Poorly developed	Well developed
8	External condyle of humerus	Transversely orientated	Less so
9	Femur	Relatively long and slender,	Much shorter than tibia, with well-marked
		without fibular groove	fibular groove
10	External cotyla of ulna	More pronounced	Less pronounced
11	Cnemial crests of tibiotarsus	Without flanges	With highly developed flanges
12	Tendinal groove of tibiotarsus	Absent	Present
13	Distal articulation of tibiotarsus:		riescht
	a, internal condyle	Bulbous	Less bulbous
	b, intercondylar fossa	Narrow	Wide
14	Fusion of tarsometatarsus	Only partial	Complete
			Complete

The characters of the new species *Enantiornis leali*, listed in 2-6a, are based on an associated coracoid, scapula and humerus (no. 4035). The species has been named after J. C. Leal, who discovered the locality and helped in the collection of material.

distal to it on the palmar side (Fig. 2a, A). At the distal end of the humerus the internal and external condyles (articulations for the radius and ulna respectively) are not well formed, the external condule being oriented more transversely (Fig. 2a, A) as in Alexornis antecedens⁴ from the Campanian (Upper Cretaceous) of Mexico. Furthermore, there is no indication of either a brachial depression or a scar for the brachialis anticus muscle. The most remarkable feature of the humeri is the variation in the area of the internal tuberosity, where four well preserved specimens show three distinct types. One has the large pneumatic foramen typical of many birds, another seems to have no such structure, while the third has what could be regarded as a pneumatic fossa with no foramen but with a canal running proximo-distally through the internal tuberosity. This third condition seems to be unique as it is unknown in any other bird or reptile. The remaining forelimb elements, although possessing unique features, are typically avian, especially metacarpals II-IV which are fused into a carpometacarpus (Fig. 2a, F). Very little can be said about the sternal fragment except that it has a keel and a large sternal notch.

The two preserved pelves are incomplete, but indicate an opisthopubic condition (Fig. 2b, C). This configuration,

generally believed to be confined to birds and ornithischian dinosaurs, has now been noted also in certain advanced coelurosaurs of the family Dromaeosauridae which, like the Enantiornithes, are of Maestrichian age. However, the large ilio-ischiadic fenestra is found only in birds. Furthermore, the smaller specimen has a synsacrum of at least nine vertebrae, a higher number than that found in coelurosaurs, and the last vertebral centrum is so tapered as to give a clear indication of a pygostyle.

The unusual morphology of the hindlimb elements might raise doubts about an avian identification. The femur (Fig. 2b, A), for example, could be said to show affinities with that of a very small theropod dinosaur in being long and slender, but in detail it seems to resemble more closely that of Archaeopteryx. The tibiotarsus (Fig. 2b, B) is very bird-like in having the astragalus and calcaneum fused to its distal end; the same is true of certain coelurosaurs, but the latter, unlike the Enantiornithes and all modern birds, still show marked suture lines between the bones involved. The distal articulation of the tibiotarsus is itself unique in that the internal condyle is larger and bulbous and the intercondylar fossa much narrower than in any modern bird.

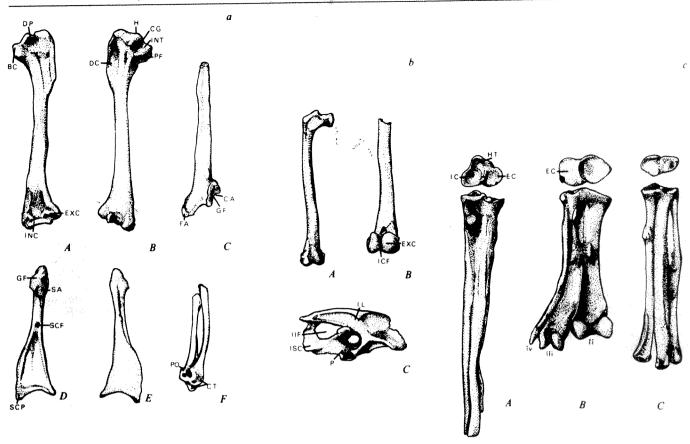

Fig. 2 a, New subclass, Enantiornithes: selected elements of pectoral girdle and forelimb. A, left humerus, palmar view; B, same, anconal view (4054); C, left scapula, external view (4039); D, left coracoid, internal view; E, same, external view (4035); F, left carpometacarpus, internal view (4049). F, ×0.6, all others ×0.3. BC, bicipital crest; CA, coracoidal articulation; CG, capital groove; CT, carpal trochlea; DC, deltoid crest; DP, depression; EXC, external condyle; FA, furcular articulation; GF, glenoid facet; H, head; INC, internal condyle; INT, internal tuberosity; PF, pneumatic fossa; PO, pollical facet; SA, scapular articulation; SCF, supra-coracoidal foramen; SCP, sterno-coracoidal process. b, Selected elements of pelvic girdle and hindlimb. A, right femur, anterior view (4037); B, distal end of right tibiotarsus, anterior view (4033); C, right side of pelvis, external view (4042). All ×0.3. EXC, external condyle; ICF, intercondylar fossa; IIF, ilio-ischiadic fenestra; IL, ilium; ISC, ischium; P, pubis. c, Three different tarsometatarsi. A, 4021 from right side (×0.5); B, 4053 from left; C, 4048 from ?right (both ×0.64). EC, external cotyla; IC, internal cotyla; HT, hypotarsus.

Three different types of tarsometatarsus are represented. The first (Fig. 2c, A), associated with a tibiotarsus, is the largest and possesses a 'primitive' avian hypotarsus (that is, one that is rectangular in proximal view). The second (Fig. 2c, B) is short and broad and lacks a hypotarsus; metatarsal II is more or less straight instead of having its distal end curving medially (the condition in most modern birds), while metatarsals III and IV are bent in the middle so that their distal ends are directed laterally. The third (Fig. 2c, C) also lacks the hypotarsus and is about the same length as the second but rather narrower, with the trochlea in a normal position; the general appearance of this third type-is distinctly coelurosaurian, except that the terminal phalanx associated with it lacks the bifurcated groove found in most-but not all-coelurosaurs (H.-D. Sues, personal communication). The most unusual feature of the first and second types of tarsometatarsus is the reduction of metatarsal IV to a lateral splint, which, although it may well have still had a toe, is attached firmly to its neighbour only proximally. The third type is somewhat different in that metatarsal IV is still substantial and attached to metatarsal III along almost its entire length. In all cases the metatarsals are not fused together completely, the sutures still being visible along much of their shafts; they are similar in this respect to Archaeopteryx and young modern birds.

It is too early to speculate as to the mode of life of these birds, but the largest forelimb elements indicate an animal with a wingspan of at least 1 m. The flying capabilities were probably limited or even non-existent as the sternum, although keeled, seems to have had a large sternal notch, and the distal articulation of the humerus is only weakly developed. The latter character and those of other forelimb elements suggest that this group of birds may have developed a form of flight, or some other method of propulsion, which differed from that of the Odontornithes (that is, Ichthyornis) and modern birds. This view is strengthened by the unique configuration of the scapulacoracoid articulation (Fig. 2a, C) and of the two ends of the humerus (Fig. 2a, A and B).

Of the hindlimb elements, only the tarsometatarsi allow one to speculate as to the possible habits of these birds. The length and narrowness of the first type (Fig. 2c, A) suggest either a wading or cursorial habit, whereas the extreme breadth and flattening of the second (Fig. 2c, B) suggest modifications for either propulsion through water and/or specialized support on land (as in the penguin). The third, more evenly broad type (Fig. 2c, C) appears to be analogous to the feet of Recent penguins; the strongly curved terminal phalanx associated with it could have been used for scrambling.

I thank Dr Bonaparte for allowing me to describe this material, the University of Tucumán for loan of the specimens, and Miss Cassandra Brown for producing the line drawings. The explorations were organized and supported by the Universidad Nacional de Tucumán, the Consejo Nacional de Investigaciones Cientificas y Técnicas and the Fundación Miguel Lillo.

Competition relatedness and efficiency

J. R. W. Harris

Natural Environment Research Council, Institute for Marine Environment Research, Prospect Place, The Hoe, Plymouth PL1 3DH, UK

Seger¹ has argued that, if a law of diminishing returns of personal fitness² with increasing consumption of a limiting resource applies, a greater increment to inclusive fitness³ may accrue to an individual by sharing the resource with its relatives than by excluding them. That is, from the point of view of an individual's inclusive fitness, there will exist an optimal relation between resource abundance, conversion efficiency (in terms of increment in personal fitness per resource unit consumed) and competitor abundance and relatedness to the subject. Here, this is rendered more concrete by deriving expressions for the optimum consumption rate for any one of a number of related individuals competing for a finite resource.

Let the selective universe consist of N individuals, among which the relatedness⁴ of the ith to the ith is z_{ij} . Let a total consumption x of a particular resource by the ith individual result in a total net reproduction for that individual of $g_i(x)$. Then, if this individual consumes an amount p_i , let the inclusive net reproduction, r_y^* , of the yth individual be defined by

$$r_y^* = \sum_{i=1}^N z_{iy} g_i(p_i)$$
 (1)

(Note that the use of 'inclusive' here does not correspond exactly to its use in the original definition of 'inclusive fitness' by Hamilton³. It avoids the necessity for a distinction between social and other effects and apparently corresponds to his earlier, heuristic usage⁵.) Differentiating and setting the derivative equal to zero yields a turning point with respect to p, when

$$g_{y}(p_{y}) = -\sum_{\substack{i=1\\i\neq y}}^{N} x_{iy}g_{i}(p_{i}) dp_{i}/dp_{y}$$
 (2)

Let the total amount of resource available to, and divided between, the N individuals be fixed, so that the p_i values are linearly dependent,

$$\sum_{i=1}^{N} dp_i/dp_y = 0, \text{ that is, } \sum_{\substack{i=1\\i\neq y}}^{N} dp_i/dp_y = -1.$$

If the individuals are ordered so that a number n, less than N, can be defined such that $dp_i/dp_y = 0$ if and only if i > n, this can replace N both in these summations and in equation (2) without loss of generality. Now, defining s_{iy} as $z_{iy}g_i'(p_i)$ and \bar{s}_{iy} as

$$\sum_{\substack{i=1\\i\neq i}}^{n} s_{iy}/(n-1)$$

equation (2) may be expanded to give

$$g'_{y}(p_{y}) = \bar{s}_{y} + \sum_{\substack{i=1\\i \neq y}}^{n} (\bar{s}_{y} - s_{iy}) dp_{i}/dp_{y}$$
 (3)

If $g_i''(p_i) < 0$ (that is, $g_i(x)$ is locally a law of diminishing returns) for $0 < i \le n$, then it is sufficient that $\mathrm{d}^2 p_i / \mathrm{d} p_y^2$ and s_{iy} are not negatively correlated for this to define a maximum. As long as $N \gg n$, so that $\sum_{i=1}^N g_i(p_i)$ is effectively independent of $g_y(p_y)$, this also defines a maximum in $r_y^* / \sum_{i=1}^N g_i(p_i)$, the proportion of the gene pool of the next generation formed by genes identical by descent to those of the yth individual.

Assumption of a particular form for $g_i(p_i)$ can yield an intuitively clearer relation. Thus, a reasonable and flexible assumption is that total net reproduction is a Michaelis-Menten function of consumption minus some maintenance factor (γ_i)

$$g_i(x) = \alpha_i \beta_i(x - \gamma_i) / (\alpha_i(x - \gamma_i) + \beta_i) : x > \gamma_i$$

$$g_i(x) = 0$$
; otherwise

so that

$$g_i'(x) = g_i^2(x)/\alpha_i(x - \gamma_i)^2$$
 (5)

In these equations, α_i , β_i and γ_i are positive constants. If $E_i(x)$ is defined by

$$E_i(x) = g_i(x)/(x - \gamma_i) \tag{6}$$

it may be conceived, in terms of Wiegert⁶, as a net efficiency of net reproduction per unit of consumption. If it is assumed that $p_i \ge \gamma_i$ for all i, that is, no individuals exist on a quota below maintenance, equation (5) may be substituted in equation (3). If, in addition, α_i , the maximum net efficiency, is constant over all individuals, the result may be expressed in terms of E_i

$$E_{y}^{2}(p_{y}) = \bar{c}_{y} + \sum_{\substack{i=1\\i\neq y}}^{n} (\bar{c}_{y} - c_{iy}) dp_{i}/dp_{y}$$
 (7)

where

$$c_{iy} = z_{iy} E_i^2(p_i)$$
 and $\bar{c}_y = \sum_{\substack{i=1 \ i \neq y}}^n \frac{c_{iy}}{(n-1)}$

If dp_i/dp_y and c_{iy} are uncorrelated, the second right-hand term of equation (7) disappears

$$E_{y}^{2}(p_{y}) = \sum_{\substack{i=1\\i\neq y}}^{n} z_{iy} \frac{E_{i}^{2}(p_{i})}{(n-1)}$$
 (8)

In the special case in which, in addition, $z_{iy} = z$ for $i \le n$ and $i \ne y$

$$E_{y}^{2}(p_{y}) = z \sum_{\substack{i=1\\i \neq y\\i \neq y}}^{n} \frac{E_{i}^{2}(p_{i})}{(n-1)}$$
(9)

That is, if an isolated population of equally related individuals can be defined, and success is to be judged in terms of some infinite, external gene pool, each should strive to raise its consumption until the ratio of its squared net efficiency to the mean square net efficiency of its competing relatives is equal to their relatedness.

In many cases, such a simple view would be inappropriate; correlations between dp_i/dp_y and c_{iy} (or s_{iy}) may be expected to be the rule. A positive correlation implies that the subject's consumption reduces most the consumption of competitors whose contribution to its inclusive fitness is thereby reduced least. As $g_{\nu}(x)$ is a law of diminishing returns, this will tend to increase optimum consumption and, under equation (4), to reduce optimum efficiency. Such an effect might be produced by a social system such as a pecking order in which the lowest members (least productive) are most affected by vagaries in consumption by those higher in the order. Hence, other things being equal, such a structure would be expected to be associated with lower population efficiencies. A spatial effect would be a common source of the converse, negative correlation, tending to raise optimum efficiency. For many organisms, consumption will tend to decline away from some 'centre of activity'. Competitor relatedness may be expected to decline similarly'; hence, the subject's consumption affects most that of those whose contribution to its inclusive fitness is most sensitive.

The negative relation of $g'_{y}(x)$ to $g_{y}(x)$ facilitates qualitative understanding of the implications of equation (3). For example,

it may be recognized that increased levels of relatedness between the individuals of a population will tend to reduce their optimal consumption, increasing their optimal net efficiency (the extent to which any one achieves this optimum depends, of course, on its competitors). Similarly, it may be seen that a reduction in the general level of individual consumption itself reduces the optimum level for any one. This immediately implies that it is adaptive for consumption to decline with increasing density of related competitors. Under equation (10), subsuming equation (5), the decline would be hyperbolic. Declines of this or a similar form have been reported for some predators and, equating hosts with the resource and oviposition with potential consumption, they are well known for insect parasitoids.

Parasitoids have also been found to emigrate in response to the presence of conspecifics⁸; as well as acting as a constraint on optimal consumption, the necessary relation of competitor numbers to individual consumption which is imposed by an overall resource limit implies that these may themselves be optimized. Thus, in the situation to which equation (9) applies, if it is further assumed that p_i is a constant, p_c , and that $g_i(x)$ is the same for all i < n $(i \neq y)$, then, from the point of view of any individual, there is an optimum density of competing relatives when $g'(p_c) = g(p_c)/p_c$. Where $g(p_c)/p_c$ may be interpreted as the gross efficiency of net reproduction per unit of consumption⁸. As $p_c \ge 0$ and $g''(p_c) < 0$ the implication is that this is maximized. Territoriality might be interpreted as the result of selection under some such relation for a population density which would be optimal for all competing individuals, although within which each will compete to increase its resource share in the manner indicated by equation (9).

Although a decline in the net efficiency of growth or reproduction at high consumption rates occurs widely 9-16, there are exceptions 17. These might indicate species for which, in response to the kind of coincidence of interests just outlined, it is the density of related competitors rather than their individual quotas which tends to vary with resource abundance, and for which there is an (evolutionary) expectation that a superfluity of resource will be utilized by an influx of related individuals, that is, inbreeding species exploiting idiosyncratic resources. In these cases, selection might act to produce an ingestive ceiling sufficiently low to veil the putative decline in efficiency.

It is the essence of these arguments that whereas in heavily outbreeding species selection will tend to maximize personal fitness, in more inbreeding ones personal fitness will tend to be sacrificed for increased 'population fitness'. It has been argued that species so adapted can only succeed if they have a fugitive way of life¹⁸. So, if the demands of inter- and intraspecies selection are to be reconciled, an association between this mode of existence and relative inbreeding would be expected; such an association seems to be found^{19,20}. In view of this, the relations derived here imply in addition that fugitive species will tend to exhibit higher net efficiencies of net reproduction per unit of resource depletion.

Conformational analysis has resulted in the design and synthesis of somatostatin analogues which show increased duration of action1-3. The introduction of covalent conformational constraints and elimination of amino acids that are not required led to the synthesis of the highly active bicyclic analogue I, cyclo(Aha-Cys-Phe-D-Trp-Lys-Thr-Cys)2.3, which showed potency equal to or greater than that of somatostatin for the inhibition of growth hormone release in vitro and in vivo, as well as for the inhibition of glucagon and insulin release in vivo (Aha, 7-aminoheptanoic acid). These results suggested that the amino acids -Phe-D-Trp-Lys-Thr- of this analogue and the corresponding residues 7-10 of somatostatin contain all the elements necessary for the expression of the above biological activities, and that the fragment -Cys-Aha-Cys- serves as a conformational constraint, allowing the tetrapeptide to attain a bioactive conformation. It was concluded that such constraint also results in the observed reduced susceptibility to metabolism by peptidases such as trypsin and has permitted both a long duration of action and oral activity2,3. If the sole purpose of the -Cys-Aha-Cys- sequence is indeed only conformational constraint, then it should be possible to design alternative, simpler constraining moieties. We have used a computer modelling and graphics system⁴ to examine possible alternative molecular fragments and report here the synthesis of a highly active cyclic hexapeptide analogue of somatostatin.

Proton NMR studies have resulted in a precisely defined model for the solution conformation of I (refs 2, 5). Because of the diminished molecular flexibility of this molecule, it has been proposed that this model may also be close to the 'bioactive conformation' (ref. 2). Using these defined coordinates and the Merck computer modelling system, analogue I was divided at the bonds indicated in Fig. 1, eliminating the -Cys-Aha-Cys-portion and leaving the tetrapeptide fragment in the 'bioactive conformation'. Various bridging units were examined as possible choices to tie together the free ends of the tetrapeptide unit. Visualization of this process was aided by the use of a structure superposition program in the Merck Molecular Modelling

Fig. 1 Cyclo(Aha-Cys-Phe-D-Trp-Lys-Thr-Cys) I, an analogue of somatostatin which shows high biological potency. For computer studies of alternate bridging groups, the molecule was separated at the bonds marked by the arrows.

For optical rotation, c = 1 in methanol. Reverse phase chromatography was used to estimate purity from the area under the curve of the UV trace at either 210 or 280 nm. Amino acids were analysed after hydrolysis for 20 h in 6 M HCl at 110 °C. Inhibition of spontaneous growth hormone release was evaluated by incubation of isolated pituocytes with somatostatin or analogue at graded doses (at least 6 doses per analogue) ranging from 10⁻¹⁰-10⁻⁵ M. Three replicate plates were used at each dose level. After 4 h incubation, growth hormone levels released into the medium were determined by a double antibody radioimmunoassay for rat growth hormone. Potency of the analogues relative to somatostatin (=1) were calculated using a relative potency formula for parallel line bioassays 12 . 95% confidence limits are given in parentheses. This bioassay is essentially as has been described elsewhere 13 . The ED₅₀ for somatostatin in this test is 5×10^{-8} M.

System called 'COMPARE' (ref. 4; Fig. 2). Among the molecular fragments examined for completion of the ring were acetyl dipeptide methylamides in the conformations defined for the various types of β -turn⁶. The resulting structure is a cyclic hexapeptide having two β -turns, a common structural occurrence as indicated by X-ray studies of cyclic hexapeptides 7.8. A least-squares fit of the terminal overlapping atoms (two atoms at one end, three at the other) was carried out without allowing any bond rotations. Fits ranging in average deviation from 0.38 to 0.61 Å were obtained for the six β -turns of types I-III and I'-III'. Better matches were attained (deviation as low as 0.10-0.31 Å) by allowing some rotation about the bond angles

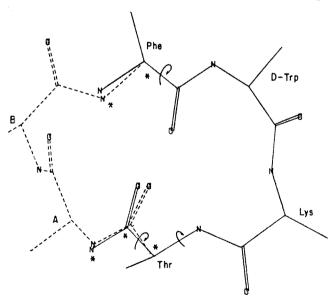

Fig. 2 Computer matching of the termini of a tetrapeptide unit and an acetyl dipeptide-N-methylamide unit having the conformation of a type 3 β -turn. The tetrapeptide unit has the conformation suggested for the -Phe-D-Trp-Lys-Thr- portion of the proposed bioactive conformation of somatostatin analogues² A least-squares fit of the atoms marked by an asterisk was carried out while simultaneously allowing rotation about the bonds marked by arrows. The average deviation of the matched atoms in this case was 0.20 Å.

indicated in Fig. 2, two of which were not defined in the study of the solution conformation of I (ref. 2).

A reasonable match in some cases led us to prepare a number of cyclic hexapeptides having the general structure cyclo(A-B-Phe-D-Trp-Lys-Thr) where A and B were chosen to fit a variety of β -turns either because they have been observed to be part of a β -turn in some X-ray study or because we thought they would be compatible with one or more of the proposed turn types. Alanine, rather than amino acids with more complex side chains, was used in combination with proline in our early analogues, on the assumption that the sole purpose of the A-B unit is conformational constraint.

The cyclic hexapeptides were prepared as outlined below:

$$\begin{array}{c} \text{H-D-Trp-Lys(2ClZ)-Thr(Bzl)-Phe-Pro-Phe-O} \\ \\ \downarrow \text{NH}_2\text{NH}_2 \\ \text{H-D-Trp-Lys(2ClZ)-Thr(Bzl)-Phe-Pro-Phe-NHNH}_2 \\ \\ \downarrow \text{(1)} \text{ i-amyl nitrite} \\ \text{(2)} \text{ $dilute 1 mg ml}^{-1} \\ \text{(3)} \text{ base} \\ \downarrow \text{(4)} \text{ HF} \\ \\ \text{cyclo(D-Trp-Lys-Thr-Phe-Pro-Phe)} \end{array}$$

The linear peptides were prepared by the solid phase method on a Beckman 990 peptide synthesizer using a protocol described elsewhere9. The cyclization procedure also follows basically the procedure described for other cyclic peptide analogues of somatostatin1. The analogues were characterized as shown in Table 1. In addition to a consistent amino acid analysis, each compound showed an appropriate NMR spectrum. The position of the γ-CH₂ of lysine is given for each compound (Table 1) as the unusual upfield shift is indicative of a proximity of the lysine and tryptophan side chains, a feature which has been postulated as important for biological activity⁵. Proximity of the two side chains was achieved in all the cyclic hexapeptides which suggests a similar conformation in this region of the various peptides.

Each analogue was evaluated for inhibition of the release of insulin, glucagon and growth hormone1. The results for inhibition of growth hormone release in vitro are given in Table 1. (For most of the low-activity analogues, all other bioassays showed no activity at the doses tested.) Table 1 shows that cyclic

^{*} Two conformers.

[†] By UV.

 $[\]ddagger c = 2.$

hexapeptides 1-3 have real activity but only low potency. However, even the most active analogue of this group (1) shows only 6% the potency of somatostatin. We considered that this low potency was due to elimination of an important contributor to receptor binding rather than a failure to attain the correct conformation for the bioactive tetrapeptide fragment. The most reasonable possibility was that we had eliminated a hydrophobic binding element. We therefore prepared several analogues incorporating phenylalanine rather than alanine in the A-B dipeptide unit (compounds 8-13 of Table 1) including an analogue (9) which constitutes cyclization of the sequence 6-11 of [D-Trp8] somatostatin. Most striking is the inhibition of growth hormone release in vitro by analogue 8 compared with that of analogue 1 (Table 1); the former is almost twice as potent as somatostatin and 29 times as potent as 1 on a molar basis. This in vitro test comes closest to measuring binding affinity as enzymatic inactivation is likely to be minimized. The fact that circular dichroism spectra of 1 and 8 in the region 190-250 (Fig. 3) are very similar indicates that these two molecules have a similar peptide backbone conformation and suggests that the higher activity of 8 results from interaction of the additional benzene ring with receptors.

The PMR spectrum of 8 shows features indicative of a high degree of molecular rigidity in the backbone and side chains. A solution conformation has been derived which will be reported elsewhere. The molecular rigidity seems to have lowered the susceptibility of this molecule to the action of trypsin, as was observed for I. Analogue 8 is cleaved by trypsin only slowly, at about the same rate as that of I in identical conditions³. The special importance of proline to the high potency of the cyclic peptide 8 is seen by comparison with 9. The increased potency of 8 seems to be due to the presence of the N-substituted cyclic amino acid not present in 9, probably through an influence on the conformation of the cyclic hexapeptide. The altered circular dichroism of 9 in the region of amide bond absorbance (200–250 nm) supports this conclusion (see Fig. 3).

The *in vivo* potency (by weight) of 8, relative to somatostatin, for inhibition of growth hormone release in rats stimulated by pentobarbital is $\sim 20-25$ (see Table 2 legend for method). (Variability in this test precludes evaluation of 95% confidence limits.) Potency (by weight), relative to somatostatin, for inhibition of insulin release is 5.2 (2.4, 11), and for inhibition of glucagon release is 8.0 (1.4, 60.2) as measured in the urethane-anaesthetized rat. (Inhibition of insulin and glucagon release was measured, relative to somatostatin (=1.0), by the ability to decrease the blood levels of glucagon and insulin in urethane-anaesthetized rats as described elsewhere 1. Saline or peptide

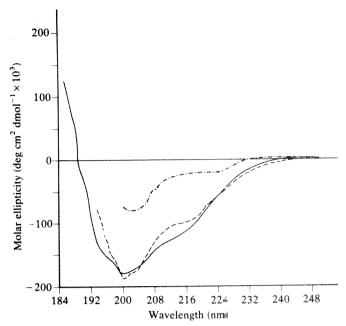

Fig. 3 Circular dichroism spectra of cyclo(Phe-Pro-Phe-D-Trp-Lys-Thr) 8 (——); cyclo(Ala-Pro-Phe-D-Trp-Lys-Thr) 1 (---); and cyclo(Phe-Phe-D-Trp-Lys-Thr) (-·-·-). All spectra taken in phosphate buffer pH 7.4.

were given by the external jugular vein and blood samples were taken 5 min later via the portal vein. Insulin and glucagon levels in the plasma were measured by radioimmunoassay.)

The duration of action of 8 is much longer than that of somatostatin and is comparable with that of the bicyclic peptide I, as shown by the inhibition of stimulated growth hormone release 5 h after subcutaneous (s.c.) injection (Table 2). We have shown that somatostatin does not reduce growth hormone levels 75 min after a 250 μ g per kg s.c. dose in this same protocol, whereas I causes significant reductions 135 min after injection of 125 μ g per kg (ref. 3). In our study, 8 has a duration comparable with that of I when evaluated simultaneously (Table 2). Both I (500 μ g per kg) and 8 (750 μ g per kg) show a statistically significant reduction in growth hormone levels 5 h after s.c. administration; 8 is also effective in inhibiting the release of growth hormone 1 and 3 h after oral administration (25 mg per kg) in this same test system (Table 2). There was no suppression

Inhibition of pentobarbital-stimulated growth hormone release was measured essentially according to a procedure described elsewhere ¹. Male Sprague-Dawley rats (190-200 g) were given saline or compound either subcutaneously (s.c.) or orally (p.o.). After the designated time period, sodium pentobarbital was given i.v. and 15 min later the rats were bled from the orbital sinus and the plasma assayed for growth hormone content by radioimmunoassay. The data are expressed as the mean ±s.e.m. (6 rats per group). The control is given for each experimental run.

when somatostatin was given orally at this dose, even after a shorter time interval (1 h), whereas the bicyclic analogue I showed statistically significant suppression of growth hormone release 1 h after oral administration at this dose, but not after

Thus, a highly active and long-acting cyclic hexapeptide analogue of somatostatin has been designed by replacing 9 of the 14 amino acids of somatostatin with a single proline. The long duration of action of this analogue could render this compound class valuable in tests of the potential application of somatostatin-like compounds in the treatment of juvenile diabetes 10,11

Oestradiol, sexual receptivity and cytosol progestin receptors in rat hypothalamus

Bruce Parsons, Thomas C. Rainbow, Donald W. Pfaff & Bruce S. McEwen

The Rockefeller University, New York, New York 10021, USA

Oestradiol and progesterone regulate feminine reproductive behaviour in rodents. Their administration induces changes of biosynthetic activity in the hypothalamus¹, one of which—the induction of progestin receptors—is correlated with the induction of sexual receptivity²⁻⁴, conveniently indicated (in the rat) by the lordosis reflex of the mounted female. We have attempted to define what might be considered as a minimal regime of oestradiol administration—one which is just 'sufficient' for activating the lordosis reflex—and have used this paradigm to measure associated changes in nuclear oestrogen (NOER) and cytosol progestin (CPRs) receptors in the mediobasal hypothalamus-preoptic area (MBH-POA) of the rat brain. We find that two 1-h exposures to oestradiol are sufficient to induce the lordosis reflex and to increase significantly CPRs in the MBH-POA. An essentially discontinuous pattern of NOERs in MBH-POA can promote these changes.

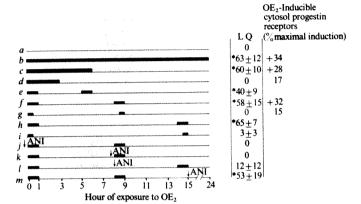

Female rats ovariectomized for 5-7 days were fitted with 5-mm silastic capsules containing oestradiol, which produced physiological levels of the hormone in serum⁴. For behaviour, each female was assigned to a separate mating group of 5-10 animals. Females received 10 mounts by male rats 24 h after initiation of oestradiol treatment. Four h before testing, each female received 500 µg P (subcutaneously (s.c.) in oil). The lordosis quotient (LQ) was calculated as: number lordoses/number of mounts × 100. Results are means ± s.e.m.

In some behavioural experiments, animals received s.c. injections of the protein synthesis inhibitor anisomycin, dissolved 20 mg ml⁻¹ in saline⁵. For all biochemical studies, four to seven samples were used for each observation, each sample consisting of MBH-POA regions from two animals. The amount of oestradiol bound to nuclear receptors in the MBH-POA was determined by using an in vitro exchange assay6. NOERs were measured 0.5, 1 and 6 h after implantation of oestradiol capsules, as well as 3 and 6 h after their removal. Results are means ±s.e.m. CPR levels in the MBH-POA were quantified using ³H-R 5020 as the radioligand for an in vitro assay⁷. CPRs were measured 24 h after insertion of oestradiol capsules, in the absence of exogenous progesterone. CPRs were measured in animals not exposed to oestradiol (controls); this binding represents a class of CPRs which is not influenced by oestradiol administration or withdrawal8. CPRs were also determined in animals which had received s.c. injections of oestradiol benzoate (15 µg daily for 3 days) to induce CPRs to maximal levels. The % maximal induction of CPRs was calculated as: (3H-R 5020 binding in experimental group) minus (3H-R 5020 binding in control group)/(3H-R 5020 binding in oestradiol benzoate) minus (3H-R 5020 binding in control group).

The effects of oestradiol treatment on sexual receptivity as measured by the LQ score indicate that a discontinuous exposure to oestradiol, in two 1-h segments, is sufficient to activate the lordosis reflex. The LQ score of animals which receive oestradiol continuously for 24 h is 63 ± 12 (Fig. 1b) and that of animals which receive oestradiol continuously for 6 h is equivalent at 24 h (Fig. 1c). However, animals which receive oestradiol continuously for 3 h are not sexually receptive at 24 h (Fig. 1d). Figure 1 (and unpublished data) demonstrates that receptivity comparable with 24 or 6 h of continuous oestradiol treatment is seen if animals receive only two 1-h segments of oestradiol, provided that the second treatment is not less than 4 nor more than 13 h after the end of the first period (Fig. 1e, f, h) ('sufficient treatment'). No receptivity is seen in animals which receive two 0.5-h segments of oestradiol (Fig. 1g, i) ('insufficient treatment').

We studied oestrogen receptor translocation following 'sufficient treatment' and found that retention of oestradiol by MBH-POA cells is transient even though this oestradiol treatment promotes delayed changes in sexual receptivity. These results may be summarized as follows: (1) The level of NOERs in MBH-POA after 1 h of oestradiol treatment resembles that seen after 6 h continuous treatment (1 h: 228±9 fmol ³Hoestradiol per mg DNA; 6 h: 197 ± 23 fmol ³H-oestradiol per mg DNA), and represents $\sim 60\%$ of the nuclear oestradiol receptor capacity⁹. (2) A second 1-h period of oestradiol treatment, beginning 7 h after the end of the first, produces NOER levels in the MBH-POA comparable with those seen after the first 1-h oestradiol period (data not shown). (3) One hour of oestradiol treatment produces at least twice the level of NOERs as does 0.5 h of oestradiol treatment $(0.5 \text{ h}: 93 \pm 11 \text{ fmol }^3\text{H}$ oestradiol per mg DNA). (4) Six hours after removal of Silastic capsules, NOER levels in the 1- and 0.5-h treatment groups decrease to ~10% and 7% of receptor capacity, respectively. Thus, an essentially discontinuous pattern of NOERs in MBH-POA is sufficient to activate the lordosis reflex at 24 h. Sufficient to activate lordosis was that NOERs in MBH-POA be elevated to 60% of their capacity, at both an early and late period, as outlined above. Six hours of continuous oestradiol treatment can be regarded as sufficient to activate lordosis because this paradigm contains two such 1-h periods.

Two classes of progestin receptors have been identified in the rat brain—one which is unaffected by oestradiol treatment, the other induced by oestradiol (ref. 8). Although the physiological significance of these two classes of progestin receptors is unclear, note that oestradiol induces progestin receptor synthesis in those areas of the brain known to mediate feminine reproductive behaviour, the MBH and POA. Moreover, a 'threshold level' (25-35% maximal induction) of oestrogen-inducible CPRs in the MBH-POA has been shown to be correlated with the appearance and disappearance of sexual receptivity4. We used several temporal paradigms of oestradiol treatment to study inducible CPRs in the MBH-POA, and found that sufficient treatment significantly elevates inducible CPRs to threshold levels in these brain regions. In animals which receive oestradiol continuously for 24 h, CPRs in MBH-POA increase from an unstimulated level of 8.1 ± 0.3 to an induced level of 12.7 ± 0.7 fmol ³H-R 5020 per mg protein. This increase of approximately 4.6 fmol ³H-R 5020 per mg protein represents a 34% maximal elevation in oestrogen-inducible CPRs, an increase to threshold levels (Fig. 1b). In animals which receive oestradiol continuously for 6 h, CPR levels in MBH-POA increase from an unstimulated level of 8.1 ± 0.3 to an induced level of 11.8 ± 1.2 fmol ³H-R 5020 per mg protein. This increase of ~3.3 fmol ³H-R 5020 per mg protein represents a 28% maximal elevation in oestradiol-inducible CPRs, also an

The effects of oestradiol (OE₂) and anisomycin (ANI) on Fig. 1 the lordosis quotient (LQ) and on the induction of cytosol progestin receptors (CPRs) in the mediobasal hypothalamus-preoptic area (MBH-POA) of the female rat. Biochemical results are expressed as % maximal induction (see text). For behaviour, animals were tested with an experienced male 24 h after the initiation of oestradiol treatment. Four hours before testing, each animal received 500 µg progesterone (s.c. in oil). In some behavioural experiments, animals received s.c. injections of the protein synthesis inhibitor, anisomycin, dissolved 20 mg ml⁻¹ in saline. For CPR measurements, animals were killed 24 h after the insertion of Silastic capsules. No exogenous progesterone was given before death. The temporal paradigms for these experiments are described below. a, No OE2, control group; b, OE2 0-24 h; c, OE2 0-6 h; d, OE₂ 0-3 h; e, OE₂ 0-1 h and 5-6 h; f, OE₂ 0-1 h and 8-9 h; g, $OE_2 0-0.5 \text{ h}$ and 8.5-9 h; h, $OE_2 0-1 \text{ h}$ and 14-15 h; i, OE_2 0-0.5 h and 14.5-15 h; j, OE_2 0-1 h and 8-9 h, ANI at -0.25 h; k, OE₂ 0-1 h and 8-9 h, ANI at 8.75 h; l, OE₂ 0-1 h and 14-15 h, ANI at 8 h; m, OE₂ 0-1 h and 8-9 h, ANI at 15 h. We conclude that a discontinuous exposure to estradiol, in two 1-h segments, is sufficient to activate the lordosis reflex and to increase CPRs in the female rat. ANI experiments demonstrate that protein synthesis essential for the activation of the lordosis reflex occurs during the period bounded by and including these two 1-h segments of OE₂ treatment. CPR levels are (fmol ³H-R 5020 per mg protein): a, 8.1 ± 0.3 ; b, 12.7 ± 0.7 ; c, 11.8 ± 1.2 ; d, 10.3 ± 0.7 ; f, 13.3 ± 1.1 ; g, 10.0 ± 0.6 . CPR levels in animals which receive oestradiol benzoate for 3 days before death (15 µg per day) are 21.1 ± 1.2 fmol ³H-R 5020 per mg protein.

increase to threshold levels (Fig. 1c). However, animals which receive oestradiol continuously for 3 h do not show threshold levels of oestradiol-inducible CPRs at 24 h (Fig. 1d); CPR levels in MBH-POA are 10.3 ± 0.7 fmol ³H-R 5020 per mg protein. CPR elevation comparable with 24 or 6 h of continuous oestradiol treatment is seen in animals which receive only two 1-h segments of oestradiol, as outlined above (sufficient treatment). CPRs in this group increase from an unstimulated level of 8.1 ± 0.3 fmol ³H-R 5020 per mg protein to an induced level of 12.3 ± 1.1 ³H-R 5020 per mg protein. This increase of ~4.2 fmol ³H-R 5020 per mg protein represents a 32% maximal elevation in oestradiol-inducible CPRs, an increase to threshold levels (Fig. 1f). Threshold levels of oestrogen-inducible CPRs are not seen in animals which receive two 0.5-h segments of oestradiol (Fig. 1g); CPRs in these animals are 10.0 ± 0.6 fmol ³H-R 5020 per mg protein at 24 h. We conclude that a discontinuous exposure to oestradiol, in two 1-h segments, is the minimum period of oestradiol treatment used which is sufficient to elevate inducible CPRs to threshold levels in the MBH-POA of the female rat. Recent work using two widely spaced (14 h) intravenous injections of oestradiol to elevate CPRs supports the notion that a discontinuous oestradiol signal can trigger CPR formation in brain and pituitary¹⁰. These data are consistent with, but not proof of, the concept that one of the neurochemical events mediated by oestradiol which accompanies the activation of behavioural receptivity is the induction of CPRs in the MBH-POA.

We also used anisomycin to demonstrate the time course of the oestradiol-induced changes in protein synthesis which are essential for the activation of the lordosis reflex. It has been shown previously that anisomycin (100 mg per kg) substantially inhibits protein synthesis in the MBH and POA of the female rat for 4 h after administration⁵. If anisomycin (100 mg per kg) is given 15 min before the first (Fig. 1j), 15 min before the second (Fig. 1k), or between the two 1-h segments of oestradiol treatment (Fig. 1l), almost no receptivity is seen at 24 h. However, if the inhibitor is given 6 h after the second period of oestradiol, no significant decrease in LQ is observed at 24 h (Fig. 1m). These data demonstrate that at least a large portion of the protein synthesis essential for the activation of the lordosis reflex is completed within 6 h after termination of the second segment of oestradiol.

The kinetics of oestradiol stimulation of uterine development have been studied by other investigators and offer parallels to our present findings. Anderson and co-workers11 found that oestradiol is retained by uterine neclei for many hours, whereas oestriol is cleared rapidly. Harris and Gorski12 showed that although multiple injections of oestriol were as effective in stimulating DNA synthesis at 24 h as a single injection of oestradiol, not all the oestriol injections were required. They suggested that the requirement for oestrogen was not continuous throughout the first 12-15 h, but only at critical phases in the response cycle. Our results suggest that there may also be a discontinuous requirement in brain for pestradiol to activate the lordosis reflex. The appearance of sexual receptivity in the female rat may be determined not only by an initial period of oestrogen-stimulated protein synthesis, but also by a later phase which may be initiated 5-14 h after the prerequisite initial oestradiol exposure.

Received 21 November 1980; accepted 14 April 1981.

^{*} LQ scores in groups a-m were compared with each other using a one-way analysis of variance. A significant treatment effect was seen (F=11.21, P<0.01). Comparisons of individual means using the Newman–Kuels tests revealed that groups b, c, e, f and h were statistically different from the control group (P<0.01).

⁺ Cytosol progestin receptor levels in groups a-d, f and g were compared with each other using a one-way analysis of variance. A significant treatment effect was seen $(F=4.91,\ P<0.05)$. Comparisons of individual means using the Newman-Kuels tests revealed that groups b, c and f were significantly different from the control group (P<0.05).

Vaccination against autoimmune encephalomyelitis with T-lymphocite line cells reactive against myelin basic protein

Avraham Ben-Nun*, Hartmut Wekerle† & Irun R. Cohen*

Despite differences in initiating events and pathophysiology, the aetiological agents of all autoimmune diseases are lymphocytes specifically reactive against normal constituents of the individual. Recently we have isolated and grown as a cell line rat T lymphocytes reactive against myelin basic protein (BP)1. This T-cell line originated from rats in which we had induced experimental autoimmune encephalomyelitis (EAE) by immunizing them against BP. Inoculation of syngeneic rats with the T-cell line led to the relatively rapid onset of EAE1. We report here that attenuation of this cell line provides an agent for establishing resistance to induction of active EAE. Intravenous (i.v.) inoculation of syngeneic rats with cells of the line attenuated by treatment with irradiation or mitomycin C augmented resistance to EAE caused by an encephalitogenic challenge with BP. Thus, aetiological agents of autoimmune disease, like those of microbial disease, when suitably attenuated can be used as effective vaccines.

EAE can be induced in susceptible animals such as rats. guinea pigs, rabbits, monkeys² or man³ by injecting them with BP emulsified in an adjuvant such as complete Freund's adjuvant (CFA). In Lewis rats the disease is characterized by paralysis that is most marked in the tail and hind limbs and which starts usually ~12 days after a single injection of BP in CFA. Histologically the central nervous system shows perivascular infiltrates of mononuclear cells⁴. Unless the rats are aged or have undergone splenectomy or thymectomy⁵ they recover spontaneously from clinical paralysis after a number of days. To study the pathophysiology of EAE we have isolated and propagated in vitro a line of Lewis rat Tlymphocytes that reacts only against BP, designated Z1a (ref. 1). We found that i.v. inoculation of as few as 105 cells of the Z1a line led to the onset of paralysis in ~4 days. Inoculation of 106 or more cells produced paralysis in ~2-3 days. Most rats recovered from this form of EAE if properly nursed during their paralysis. Table 1 shows the specificity of the proliferative response of the anti-BP Z1a line compared with that of the Z1c line which had been selected for its reactivity against another antigen, the purified protein derivative (PPD) of the mycobacteria present in CFA. The cells of each line responded to its specific antigen, and were also activated by the T-cell mitogen concanavalin A (Con A). Essentially all the cells in both the Z1a and Z1c lines proved to be positive for a T-cell marker using a specific monoclonal antibody (Sera-lab, UK; clone W3/13 HLK) immunofluorescence assay6.

We investigated the effect of attenuating the Z1a line by inhibiting its cell division. Table 2 shows that i.v. injection of 1×10^7 untreated cells of the Z1a line into syngeneic Lewis rats produced EAE in 18 of 20 rats within 2-3 days. Irradiation of the cells with 1,500 rad or treatment with mitomycin C, agents that block cell division, abrogated the ability of these cells to cause EAE. None of 25 rats that received Z1a cells treated in this way developed EAE. Furthermore, inoculation of

Table 1 Anti-BP and anti-PPD T-cell lines are immunospecific

	Proliferative response (c.p.m. $\times 10^{-3} \pm s.d.$)						
T-cell line	No antigen	BP	PPD	Con A			
Anti-BP (Z1a)	1.7 ± 0.3	48.7 ± 6.1	1.9 ± 0.4	71.4 ± 9.2			
Anti-PPD (Z1c)	1.4 ± 0.7	1.2 ± 0.4	77.9 ± 10.4	82.3 ± 12.7			

The Z1a and Z1c cell lines originated from the same draining lymph node cell population obtained from female Lewis rats immunized with BP in CFA as described elsewhere 1. To develop the cell lines, Lewis rats were injected in each footpad with 0.05 ml containing BP ($25 \mu g$, extracted from guinea pig spinal cords¹⁰ emulsified in equal volumes of phosphate-buffered saline and CFA containing 4 mg ml 1 of Mycobacterium tuberculosis H₃₇Ra (Difco). On day 9, the draining lymph nodes were removed and a single-cell suspension prepared. The cells were then selected in vitro for BP or PPD by culturing them with either antigen for 72 h. The lymphoblasts that were generated were separated by a discontinuous Ficoll gradient and propagated and maintained in vitro as a cell line for several months in medium enriched with T-cell growth factor as reported elsewhere¹. The proliferative responses of the T-cell lines were tested *in vitro* as follows¹. Briefly, 2.5×10^4 cells of either Z1a or Z1c cells were cultured in quadruplicates in flat-bottom microtitre wells in 0.2 ml of Eagle's medium supplemented with 1% fresh autologous rat serum, 2-mercaptoethanol (5×10^{-5} M), L-glutamine (2×10^{-3} M) and antibiotics (streptomycin and penicillin) with added irradiated (1,500rad) normal syngeneic lymph node cells as accessory cells $(5 \times 10^6 \text{ cells ml}^{-1})$ and antigens, BP $(50 \mu \text{g ml}^{-1})$, or PPD $(25 \mu \text{g ml}^{-1})$; Staten Serum Institut) or Con A $(2.5 \mu \text{g ml}^{-1})$; Miles-Yeda, Israel). After 24 h the cultures were pulsed with ³H-thymidine $(1 \mu \text{Ci per well, specific})$ activity 10 Ci mmol⁻¹; Nuclear Research Centre, Israel) for 16 h. The cells were then collected on glass fibres using an automatic collector and thymidine incorporation measured in a liquid scintillation counter.

untreated cells of the Z1c line also failed to induce EAE. Thus, induction of EAE is a function of the specific anti-BP Z1a line, a property lost after irradiation or treatment with mitomycin C.

We then tested whether inoculation with cells incapable of inducing EAE could affect the susceptibility of rats to active induction of EAE by later challenge with BP in CFA. Table 3 shows that untreated Lewis rats were highly susceptible to induction of EAE on injection with BP in CFA; 69 of 71 rats developed disease. Intravenous inoculation of cells of the Z1c anti-PPD line, either untreated or irradiated, did not affect this susceptibility and EAE was induced in all 20 rats challenged with BP in CFA. In contrast, a single i.v. injection of 1×10^7 Z1a cells attenuated by treatment with mitomycin C or irradiation led to significantly increased resistance to induction of EAE. Only 14 of a total of 40 rats showed any signs of paralysis and the degree of the paralysis in these rats was judged to be much milder than that appearing in the other groups. Thus it seems that vaccination with attenuated autoimmune T lymphocytes

Table 2 Attenuated T lymphocytes of the Z1a anti-BP line do not produce EAE

	Inoculation of T-cell lines				
Line	Treatment	Incidence of EAE			
Anti-BP (Z1a)	Untreated Irradiated	18/20 0/15			
	Mitomycin C	0/10			
Anti-PPD (Z1c)	Untreated	0/20			

Healthy female Lewis rats (2–3 months old) were injected i.v. with 1×10^7 cells of T-lymphoblast cell lines specifically reactive against BP (Z1a) or PPD (Z1c). Before inoculating the cell lines into normal syngeneic animals, they were re-stimulated in vitro with the relevant antigen, in the presence of irradiated (1,500 rad) syngeneic accessory cells for 72 h (ref. 1). The cells, >80% lymphoblasts, were then collected and injected, either untreated or attenuated by irradiation (1,500 rad) from a ^{60}Co source, or treatment with mitomycin C (50 μg per 10^7 cells per ml; Sigma) at 37°C for 40 min. The treated cells were washed extensively before being inoculated. EAE was diagnosed clinically by overt paralysis of the hind limbs and histologically by perivascular mononuclear cell infiltration of the central nervous system 4 .

Table 3 Attenuated anti-BP T-cell line vaccinates rats against induction of EAE

Vaccination with T-cell line	Incidence of EAE in response to injection of BP in CFA	% Inhibition of EAE
None	69/71	
Anti-PPD (Z1c) Untreated Irradiated	10/10 10/10	0
Anti-BP (Z1a) Irradiated Mitomycin C	8/25* 6/15*	68 60

EAE was induced in naive Lewis rats (2-3 months old) or in animals that had been vaccinated i.v. 3 weeks earlier with 107 cells of the anti-PPD Z1c T-cell line or with cells of the anti-BP Z1a T-cell line that were either irradiated (1,500 rad) or treated with mitomycin C, as described in Table 2 legend. EAE was induced by injecting BP in CFA into the hind footpads of the animals, as described in Table 1 legend. *P < 0.001.

provided protection against active EAE for about 65% of the

We do not know the mechanism by which the attenuated T lymphocytes increased resistance to induction of EAE; however, it seems reasonable to suspect that some process of immunity was involved. The Z1a anti-BP lymphocytes probably differed from the ineffective Z1c anti-PPD lymphocytes in the structure of their antigen receptors (Table 1). Antigen receptors of Tlymphocytes⁷ as well as of Blymphocytes or antibodies⁸ can be immunogenic. Immunity against antigen receptors, antiidiotypic immunity, has been proposed to serve as a mechanism that regulates immune responses by suppressing or activating specific clones of lymphocytes bearing the target receptors. Vaccination with attenuated Z1a cells might have produced an immune response against endogenous clones of lymphocytes with anti-BP receptors. As anti-BP clones are the aetiological agents of EAE, development of the disease would be inhibited. Therefore, our results could be explained by anti-receptor immunity raised against the autoimmune lymphocytes that mediate EAE. However, other explanations are possible and the anti-receptor hypothesis must be tested experimentally.

Whatever the mechanism of protection, the procedure described here can be conceptually related to vaccination against infectious diseases in which inoculation of an attenuated agent of disease induces a degree of protection against the virulent pathogen. In the case of autoimmunity, the aetiological agent of disease is not a microbe, but arises within the immune system of the individual. Our results indicate that an artificially induced autoimmune disease may be mitigated or prevented by vaccination against specific effector lymphocytes. A different but related problem is posed by the need to treat the spontaneous, often chronic processes that characterize the important autoimmune diseases of man.

C-terminal sequence of the secreted form of mouse IgD heavy chain

Renate Dildrop & Konrad Beyreuther

Institut für Genetik der Universität zu Köln, D-5000 Köln, 41, FRG

Immunoglobulins have been identified as membrane-bound molecules on the surface of B lymphocytes and as secreted products of plasma cells. In the case of immunoglobulin M(IgM) the carboxy-terminal sequences of the μ -chains of membranebound and secreted molecules differ from each other and are encoded by different exons of the μ constant region ($C\mu$) gene. The coding sequence for the C-terminus of the secreted μ -chain is contiguous with the 3' end of the Cµ4 exon and separate exons downstream of Cµ4 encode the C-terminus of the membranebound chain¹⁻³. Immunoglobulin D is also found membranebound and as a secreted molecule, and recent data indicate that the exon arrangement of the Cô gene is in part similar to that of the Cµ gene4.3. However, the amino acid sequence analysis presented here demonstrates that in the case of IgD the Cterminus of the secreted δ-chain is encoded by a separate exon (the CoDC exon of Tucker et al.5) and not by the CoAC sequence which corresponds topographically to the sequence expressed at the C-terminus of secreted µ chains.

The cell line B1-8. δ 1 (IgD, λ 1) has been isolated as a switch variant of the cell line B1-8.64.1 (IgM, λ 1) and is of C57BL/6 origin⁶. It secretes a monoclonal IgD antibody with specificities for the hapten (4-hydroxy-3-nitrophenyl)acetyl (NP). Anti-NP antibodies from B1-8.81 ascites fluid were purified by affinity chromatography⁶. The heavy chains of these molecules are linked to each other and to the light chains by disulphide bridges (ref. 6 and unpublished data). After complete reduction and carboxyamidomethylation the heavy and light chains were eluted from Sephadex G-100 with 4.5 M urea, 1 M propionic

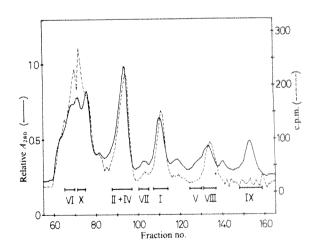

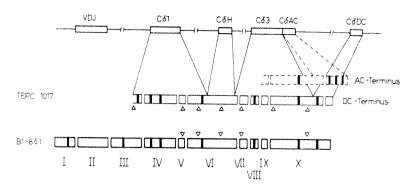

Fig. 1 Gel filtration of cyanogen bromide-cleaved peptides of 14 C-carboxyamidomethylated B1-8. δ 1 heavy chain. Cyanogen bromide cleavage of 50 mg of the completely reduced and alkylated heavy chain was performed in 70% formic acid at a concentration of 10 mg ml⁻¹ with a fivefold excess (w/w) of CNBr for 24 h at 20 °C. The mixture was dried under a stream of nitrogen. The peptides were dissolved in 3.5 ml of 0.1 M formic acid containing 6 M deionized urea and applied to a Sephadex G-50 superfine column (2×200 cm) equilibrated in the same solvent. Fractions of 3.3 ml were collected and aliquots of $20~\mu l$ were used for liquid scintillation counting in 5 ml of Bray's solution 10 . Roman numerals of the pooled fractions refer to the position of the corresponding peptides in the sequence of the B1-8.81 heavy chain as given in Fig. 2. Peptide no.III was insoluble in 6 M urea, 0.1 M formic acid, and could thus be isolated without chromatographic separation.

acid. The isolated heavy chains were treated with cyanogen bromide and peptides were separated by column chromatography on Sephadex G-50 (Fig. 1). Column fractions containing more than one peptide were rechromatographed on either Sephadex G-100 or Sephadex G-50. The purified CNBr fragments of the δ heavy chain were characterized by end group and compositional analysis and carbohydrate and cysteine contents (cysteines were labelled with ¹⁴C-iodoacetamide during reduction and alkylation, carbohydrate was detected as glucosamine in amino acid analysis).

The published IgD heavy-chain DNA sequence⁵ enabled us to identify all constant-region CNBr fragments. They correspond to the C δ 1, C δ H and C δ 3 exons as defined by Tucker et al. (Fig. 2). Five of the seven predicted⁵ carbohydrate attachment sites carry sugar, except the first proposed site in C δ 1 and the second one in C83. The lack of carbohydrate in the first proposed site in C81 can be deduced from the absence of carbohydrate from CNBr fragment III of the B1-8.δ1 chain. It is known that the sequence asparagine-phenylalanine-threonine is not necessarily used as a carbohydrate attachment site7. However, our determination of radioactive iodoacetamide incorporation (data not shown) indicates that the CNBr fragment III also does not contain the cysteine residue expected in position 5 of C δ 1 (Fig. 2). If the 5' intron-exon junction of C δ 1 were defined not by the third RNA splice site proposed by Tucker et al.5 but by the fourth site situated 22 nucleotides further downstream 1 the Cδ1 domain would be shortened by seven amino acids and lack both cysteine and carbohydrate attachment site. Alternatively, the lack of these two structures in the B1-8.81 CNBr fragment III could reflect an allotypic difference between the δ -chains from C57BL/6 and those of BALB/c from which the TEPC 1017 tumour⁵ originates.

The protein sequence of the second carbohydrate attachment site in $C\delta 3$ is conserved in the B1-8. $\delta 1$ heavy chain, but not used for carbohydrate attachment. Neither the predicted C-terminal CNBr fragment of the AC-gene segment nor that of the DC-exon was identified (Fig. 2). This can be explained by a base pair exchange in the corresponding methionine codon, representing a sequence difference between B1-8. $\delta 1$ and TEPC 1017 δ -

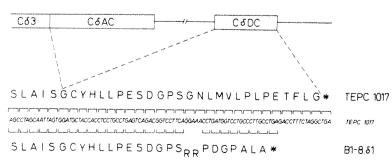

Fig. 3 Sequence of the C-terminal part of secreted B1-8.δ1 heavy chain. The C-terminal sequence of IgD heavy chains from TEPC 1017 and B1-8.δ1 are aligned to the corresponding TEPC 1017 exons and cDNA sequence. The TEPC 1017 sequence was taken from ref. 5. The B1-8.δ1 sequence was obtained by automated Edman degradation of tryptic peptides using an updated Beckman 890 B sequencer. Degradations were performed in the presence of 3 mg of the non-protein carrier Polybren 12 using a 0.2 M Quadral program 13. Phenylthiohydantoin derivatives obtained after conversion using the Sequemat P6 autoconverter were identified by HPLC 14 and TLC 15. The C-terminal nine amino acids of B1-8.δ1 are different from the TEPC 1017 cDNA sequence but not from the sequence deduced from the germ-line DNA 8. The cDNA and germline DNA sequence differ by one inserted and one exchanged nucleotide. A key to the single letter amino acid code is provided by Dayhoff 16.

Fig. 2 Schematic representation of the CNBr-cleaved peptides in the sequence of the secreted B1-8. δ 1 heavy chain. The genomic organization of the C δ gene according to Tucker et al.⁵ is given at the top of the figure. The translated TEPC 1017 cDNA sequence is schematically represented by CNBr-peptides (open boxes). The positions of cysteines (black bars) and of putative carbohydrate attachment sites (open arrow heads) are indicated. Hypothetical CNBr-fragments corresponding to a chain which would terminate with the AC-segment are shown as dashed lines. The alignment of the CNBr-fragments of the B1-8. δ 1 heavy chain is given in the lower part of the figure. Alignment of peptides I-III is according to Bothwell et al.¹¹. No carbohydrate was found in peptide III and in the N-terminal tryptic peptide of X. Peptide III contains only one cysteine.

chains. If the AC-gene segment were expressed in the secreted form of the δ heavy chain the loss of the cyanogen bromide cleavage site would result in a new CNBr fragment containing four cysteines. By comparing the amount of incorporated radioactivity with that of other cysteine-containing peptides, the CNBr fragment X, the only candidate for the C-terminus, was found to contain only two cysteines. This would be expected if the DC-segment is expressed in the secreted B1-8. δ 1 heavy chain.

Tryptic peptides of this CNBr fragment were separated on Sephadex G-50 in 0.5 M formic acid and further analysed by automated Edman degradation. The sequence of the C-terminal 27 amino acids is presented in Fig. 3. The sequence data clearly show that the C-terminus of the secreted B1-8. δ 1 heavy chain is encoded by the C δ DC exon. The sequence of the C-terminus is identical to that predicted by the sequence of the TEPC 1017 cDNA in the C-terminal 5 amino acid positions of C δ 3 and the first 13 positions of C δ DC. The last nine residues of the B1-8. δ 1 heavy chain do not fit the predicted sequence at all. This problem can be resolved, however, by exchanging in the TEPC 1017 DNA a single base pair and inserting another one (note that both changes occur in the upper part of a possible hairpin structure). The resulting frameshift generates the B1-8. δ 1 C-terminal heavy-chain sequence.

It is now clear that the difference between the cDNA-derived TEPC 1017 C-terminal δ -chain sequence and the sequence of the B1-8. δ 1 chain C-terminus is not due to genetic polymorphism. Tucker et al. have very recently isolated the C δ DC exon from BALB/c liver DNA and found that it encodes an amino acid sequence identical to that expressed in the C-terminus of the B1-8. δ 1 chain. Thus, the TEPC 1017 tumour line has either accumulated somatic mutations in the C δ gene or, more likely, the difference between cDNA and germ-line gene sequences is due to errors in DNA-RNA or RNA-DNA transcription. Taken together, our results show that the C-terminus of the secreted δ -chain is encoded by the C δ DC exon and that C δ AC-encoded sequences are not expressed in the secreted δ -chain. B1-8. δ 1 cells also carry IgD on the surface and the surface-bound δ -chains have a higher molecular weight than the

secreted ones⁶. It seems likely that, as in the case of IgM, the C-termini of the two chains differ from each other and an as yet unidentified exon encodes the C-terminus of the surface-bound δ-chain.

This work was initiated by M. S. Neuberger who also supplied the B1-8.81 protein. We thank K. Rajewsky for stimulating discussions during the work and preparation of the manuscript, and G. Zimmer and K. Neifer for technical assistance. This work was supported by the Minister für Wissenschaft und Forschung des Landes Nordrhein-Westfalen through a Forschungsbeihilfe to K.B. and K.R. and by the Deutsche Forschungsbemeinschaft through SFB 74 to K.B.

SV40 T antigen binds specifically to a cellular 53 K protein in vitro

Frank McCormick*, Robin Clark†, Ed Harlow* & Robert Tjian†

* Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK

† Department of Biochemistry, University of California, Berkeley, California 94720, USA

Simian virus 40 (SV40) large T antigen is a multifunctional protein that is essential for virus replication and the establishment and maintenence of cell transformation1. The molecular basis of these functions probably involves specific interactions of T antigen with DNA²⁻⁴ and cellular proteins. An example of such an interaction has been described recently; a significant fraction of the T antigen extracted from cell lysates is tightly bound to a cellular phosphoprotein of molecular weight 53,000 (53K)⁵⁻⁹. Here we demonstrate in vitro the direct interaction of highly purified T antigen (D2 T antigen or SV80 T antigen) with 53K in lysates from a variety of mouse cell lines. All the 53K detected in these lysates was able to bind to added T antigen, and it was the only cellular protein with which T antigen formed a stable complex. We conclude that 53K binds directly to a specific site on T antigen and that binding occurs without previous modification and without involvement of other virus-encoded or induced proteins.

The function of 53K is unknown, but several interesting properties have been attributed to this protein in addition to its association with large T antigen. Transformed cells seem to express significantly higher levels of 53K than normal cells^{6,10}. Similarly, SV40-infected mouse or monkey cells synthesize 53K more rapidly than uninfected cells^{9,11}. Furthermore, lymphocytes freshly prepared from the spleens of young mice express

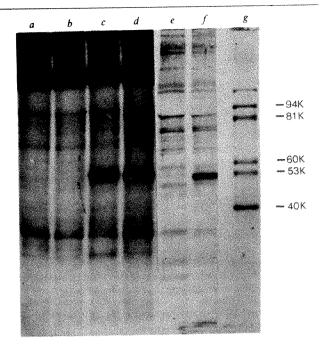

Fig. 1 Binding of purified D2 to 53K in vitro. F9 mouse embryonal carcinoma cells (supplied by P. Goodfellow) were labelled with ³²P-labelled inorganic phosphate (1 mCi ml⁻¹ phosphate-free medium) or ³⁵S-Met (1 mCi ml⁻¹ Met-free medium) as described elsewhere7. Monolayers were washed with phosphate-buffered saline and cells lysed in buffer A (2% NP-40, 10 mM Tris, 140 mM NaCl, pH 8.0; 4 °C for 15 min). These lysates were centrifuged for 2 min in an Eppendorf microfuge and the supernatants used as a source of labelled 53K. D2 protein (1 µg of purified protein) were added to lysates corresponding to ~2×10° F9 cells in 200 µl extraction buffer. After incubation at room temperature for 15 min, 5 µl of preimmune rabbit serum was added and incubated at 4 °C overnight. Rabbit immunoglobulin G (IgG) was removed with 50 μl of 10% fixed Staphylococcus aureus. The remaining solution was immunoprecipitated and immune complexes were washed twice in buffer A and twice in 2 M urea, 0.4 M LiCl, 10 mM Tris, pH 8.0, and subjected to SDS-polyacrylamide gel electrophoresis as described elsewhere 18 . Tracks a-d are from cells labelled with 32 P-phosphate; tracks e-f are from 35 S-labelled cells. Track g is a molecular weight marker mix. a, 5 µl preimmune rabbit serum; b and e, 5 μ l anti-D2 serum; c and f, 5 μ l anti-D2 serum in the presence of 1 μ g D2 protein; d, anti-53K serum F5 (ref. 7).

detectable levels of 53K only after mitogenic stimulation with an agent such as concanavalin A12. Another interesting observation is that some mice bearing SV4D-induced tumours raise autoantibodies against 53K^{5,8}. Because 53K synthesized by SV40-transformed or infected cells becomes complexed with large T we are interested in determining how these proteins interact and whether this interaction relates to the role of large T in promoting DNA synthesis 13.14, negulating early mRNA synthesis 15-17 and in cellular transformation (see discussion in ref. 1).

Here we describe investigations of the mechanism of binding of SV40 large T with 53K in an in vitro system. We have used the adenovirus: SV40 hybrid protein D2 as a convenient source of T antigen and have assayed for the ability of purified D2 protein to bind radiolabelled 53K in detergent lysates from various cells. In early experiments, 3T6 cells were used. However, the F9 line of embryonal carcinoma cells seems to express significantly more 53K and was therefore used here.

Purified D2 protein was added to lysates of labelled F9 cells and incubated at room temperature for 15 min. It was then immunoprecipitated from these lysates using antiserum raised against purified D2 protein or with monoclonal antibodies which recognize a single determinant on the protein. It is clear from Fig. 1 that anti-D2 antibodies immunoprecipitated a 53K phosphoprotein from those lysates to which D2 protein had

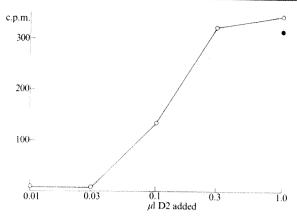

Fig. 2 Titration of D2 against 53K. Various concentrations of D2 protein were added to lysates of ³⁵S-Met-labelled F9 cells. The amount of 53K immunoprecipitated by monoclonal antibodies against D2 was estimated by cutting the 53K bands from a dried gel and counting them in a liquid scintillation system. In these immunoprecipitations, monoclonal antibodies which recognize a determinant on D2 protein were used. The hybridoma cells which produce these antibodies were obtained by fusing spleen cells from BALB/c mice bearing SV40-induced tumours with the myeloma line P-3-NS1-1Ag-4-1. These mice had been given an injection of partially purified T antigen/53K complex 3 days before spleen removal. Details of this and other hybridoma cell lines will be described elsewhere ¹⁹. One of these lines, L21, produces antibodies directed against 53K¹⁹.

been added. In the absence of added D2 protein, no cellular proteins were precipitated specifically. Similar results were obtained with T antigen purified from SV80 cells. These results suggest that the added T antigen binds to labelled 53K in these lysates and thus allows its immunoprecipitation by antisera that have no detectable activity against 53K itself. The 53K protein that seemed to bind to T antigen was not released during stringent washing of immune complexes with buffers containing 0.5% NP-40, 0.4 M LiCl or 2 M urea. In these conditions, no other labelled cellular proteins were immunoprecipitated specifically in association with T antigen. Thus the complex

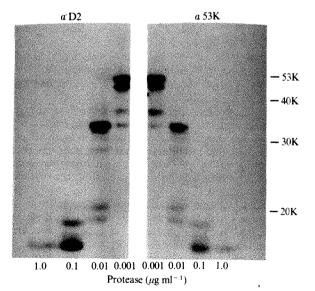

Fig. 3 V8 protease digestion of 53K. 53K was immunoprecipitated directly with monoclonal antibodies against 53K (from hybridoma clone L21) or indirectly by monoclonal antibodies which recognize D2 (clone L7) in the presence of added D2 protein. Immunoprecipitates were treated as described in Fig. 1 legend and the 53K bands removed from gels electrophoretically. Aliquots of the labelled protein were digested with various concentrations of V8 protease and again subjected to SDS-PAGE¹⁸.

formed in vitro resembled that extracted from SV40-transformed 3T3 cells⁷. We can also conclude that the polypeptide sequences which large T shares with small t are not required for binding, as these sequences are not represented on D2 protein, and that the mutation on SV80 T antigen which destroys its ability to initiate SV40 DNA synthesis (Gish and Botchan, personal communication) does not affect its ability to bind 53K.

When increasing concentrations of D2 protein were added to a constant volume of F9 cell lysate, the amount of 53K immunoprecipitated by anti-D2 antibodies was proportional to the amount of D2 T antigen added (Fig. 2). The maximum amount of 53K that could be detected by this indirect immunoprecipitation assay corresponded closely to the maximum amount that could be immunoprecipitated directly by a monoclonal antibody against 53K. Thus, all the immunologically reactive 53K from these cell lysates seemed to be available for binding to added D2.

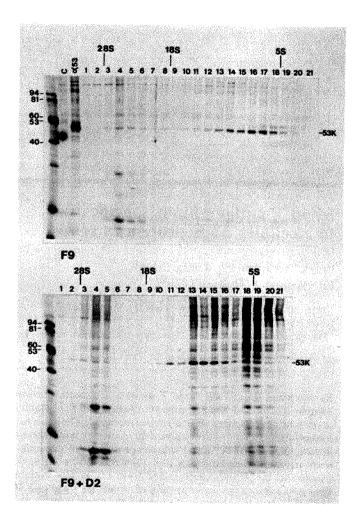

Fig. 4 Sedimentation of 53K in the presence of added D2 protein. F9 cells were labelled with ³⁵S-Met (0.24 mCi ml⁻¹, 2 h) and lysates from these cells were incubated at 22 °C in the presence (lower panel) or absence (upper panel) of D2 protein (2 μg per ml lysate). Each lysate was centrifuged at 25,000 r.p.m. through sucrose gradients as described elsewhere and each fraction was immunoprecipitated with 10 μl L21 anti-53K hybridoma supernatant. Immune complexes were treated as in Fig. 1 legend. Tract C in the top panel represents an immunoprecipitation of unfractionated, untreated F9 lysate with anti-alkaline phosphate monoclonal antibodies. Track 53K represents immunoprecipitation of the same lysate with anti-53K antibodies.

The 53K species immunoprecipitated directly by antibodies was compared with the 53K species that formed a stable complex with D2 protein. Figure 3 shows that the products of partial proteolysis generated by addition of V8 protease were identical for the two 53K samples, which suggests that these are closely related if not identical, proteins.

We have done similar in vitro binding assays using lysates from a variety of cell lines: these include 3T3 cells transformed by polyoma virus⁵, 3T6 cells infected with wild-type polyoma virus, mouse L-cells and 3T6 cells. In each case, a single polypeptide of molecular weight (MW) 53,000 was immunoprecipitated by anti-D2 sera after addition of T antigen to the respective lysates (data not shown). The availability of 53K for binding in these cell lysates suggests that other proteins in the lysates, for example, polyoma virus T antigen, do not compete effectively for binding with SV40 large T.

The data described here provides direct evidence that purified antigen added to lysates of cells expressing 53K is able to form a complex with this protein. We have further demonstrated this association by determining the sedimentation properties of 53K in the presence and absence of D2 protein. Figure 4 shows that most of the 53K extracted from F9 cells sediments at ~8S, corresponding to a molecular weight of the order of 200,000. This could represent a tetrameric structure, or an association of 53K with other macromolecules. A small fraction of the 53K from these cells sediments at 20S, which suggests a native molecular weight of up to 1 million. It is unclear whether this represents homopolymers of 53K or a high-molecular-weight complex which contains other components. After addition of D2 protein to lysates of F9 cells, the lower-molecular-weight form shifted to a sedimentation value of 12S, which corresponds to a native molecular weight of ~300,000. Similar results were obtained when either anti-53K or anti-D2 antibodies were used to immunoprecipitate the complex. These results suggest that one molecule of D2 protein binds to a 200,000-MW form of 53K or these conditions. It should be stressed, however, that these sedimentation values cannot be used to determine molecular weights with a high degree of reliability, as the sedimentation properties of proteins are affected by their configuration and gradients of the type described here do not provide high resolution. Nevertheless, it is clear that the addition of D2 protein to lysates of F9 results in a significant increase in the molecular weight of 53K in its native state which indicates a physical association of the two protein species.

We have been able to demonstrate the binding of SV40 T antigen to a cellular 53K protein in vitro, by two independent methods. The development of this system should allow us to assess whether binding of 53K affects the biochemical activity of T antigen and thus modifies its biological functions.

We thank D. Lane for anti-D2 serum and Michael van Wilde, Kit Osborne and Alan Robbins for growth of cells. During part of this work study, F. M. held an ICRETT Travel Fellowship from UICC, Geneva. E. H. is a fellow of the Lady Tata Memorial Trust.

Persistence and expression of histone genes injected into Xenopus eggs in early development

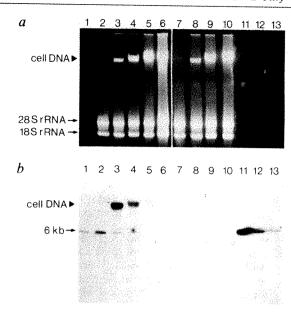

Mary M. Bendig

Institut für Molekularbiologie II der Universität Zürich, Hönggerberg, 8093 Zürich, Switzerland

Microinjection of amphibian oocytes with purified cloned DNA has proven to be a valuable assay system for studying eukaryotic gene expression¹⁻¹³. The oocyte's ability to express microinjected genes has already allowed a functional analysis of several genes and their sequence manipulated counterparts 14-20. Although such studies are now possible with several other expression systems, the oocyte system is unique in that it represents a cell destined, on fertilization, to divide and differentiate into an embryo. Thus, it was envisaged that the technique of microinjecting genes and their mutant analogues into fertilized eggs might eventually be used as an assay system for studying the transcriptional control processes that occur during cell differentiation and development. To this end, fertilized eggs of Xenopus laevis were injected with a cloned repeat of sea urchin histone genes and the fate and expression of the injected genes examined during the early stages of Xenopus development. After replication during the early cleavage stages. the injected sea urchin histone DNA sequences persisted to at least the swimming tadpole stage. The injected genes were also at least in part faithfully transcribed into RNA species with the correct histone mRNA 5' and 3' termini. Thus, these results, reported here, meet the prerequisites for an assay system capable of being used to investigate the factors involved in the developmental control of gene activity.

Fertilized eggs were injected with sea urchin histone DNA in one of two forms—as a linear 6-kilobase (kb) HindIII fragment recovered from the recombinant h22 (ref. 21) or as supercoiled, circular pBR322 recombinant plasmid DNA containing two copies of the 6-kb HindIII fragment tandemly integrated head to tail. The h22 repeat contains all five histone genes and transcription of all five proceeds in the same direction²². Nucleic acid was isolated from the developing embryos at various stages post-injection and the persistence and physical state of the injected DNA sequences were analysed by blot hybridization. In Figs 1 and 2, each gel slot was loaded with a sample representing one embryo equivalent of nucleic acid isolated at the indicated stage of development. The hybridization probe was 32P-labelled pBR322 recombinant plasmid DNA containing the coding region of the sea urchin H1 histone gene. This H1 probe was chosen because, in contrast to the entire repeat, it gave no background hybridization to nucleic acid samples prepared from uninjected embryos (Fig. 1, lanes 7-10). Clear hybridization is seen in developing embryos after injection of either linear (Fig. 1) or circular DNA (Fig. 2). Moreover, the injected DNA sequences were replicated in the early stages of development, consistent with, and extending, the recent report that DNA injected into unfertilized eggs supports semiconservative replication of the injected DNA²³. Thus, by comparing lanes 2 and 3 in Figs 1 and 2 with known amounts of DNA (Fig. 1, lanes 11-13; 2,500, 250 and 25 pg, respectively), clearly there is at least a 10-fold increase in the amount of hybridizable sequences in the embryo at late blastula as compared with the amount in the egg immediately following injection. As the embryos developed further, the amount of hybridizable DNA per embryo steadily decreased, presumably reflecting selective degradation of the injected DNA (Figs 1, 2, lanes 3-6). However, faint amounts of injected DNA sequences were detectable as late as the swimming tadpole stage following injection of linear DNA (Fig. 1, lane 6) and as late as the early

Fig. 1 Analysis by DNA blotting of the persistence and physical state of injected DNA sequences in developing embryos of X. laevis following the injection of fertilized eggs with linear molecules of sea urchin histone DNA. Artificially fertilized eggs of X. laevis were prepared as described by Billet and Wild²⁹. Mature male and female frogs received two priming doses of Pregnyl (Organon). Eggs were squeezed out through the cloaca and fertilized immediately with a freshly prepared suspension of sperm. After chemical decapsulation with papain, healthy, fertilized eggs were injected within 1 h, before the first cleavage event occurred. The microinjection technique was essentially the same as used for oocytes^{1,2}, except that in the fertilized egg the germinal vesicle has disappeared and direct nuclear injection is not necessary. A linear 6-kb HindIII fragment containing the histone gene repeat of P. miliaris was recovered from the recombinant λ h22 (ref. 21) and purified by actinomycin/CsCl gradient centrifugation. In most experiments, 250 pg of DNA in a volume of 10 nl was injected per egg. Eggs injected with 500 pg of DNA did not develop beyond the late blastula stage. According to previous reports, however, even after injection of 2-4 ng of DNA, 15% of the embryos reached the feeding tadpole stage³⁰. About 2 h after injection, embryos, usually now at the four-cell cleavage stage, were transferred from Barth's medium to sterile 'aged' water plus antibotics (Gibco) and the developing embryos incubated at 18 °C. Samples of 5-10 embryos were collected immediately following injection and at the indicated stages of development³¹ up to and including the swimming tadpole. Embryos were homogenized at 0 °C in 10 mM EDTA, 100 mM Tris-HCl (pH 7.5), 300 mM NaCl, 1 mg ml⁻¹ proteinase K and 2% w/v SDS. After a 30-min incubation at room temperature, the homogenate was phenol-extracted three times, chloroform-extracted twice and the nucleic acids precipitated with two volumes of ethanol. The equivalent of one egg or embryo's worth of nucleic acid isolated from progressive stages of development was electrophoresed

through a 0.8% agarose gel. The gel was stained with ethidium bromide and photographed (panel a). To obtain efficient blotting of supercoiled, circular DNAs and large molecular weight DNAs, the gel was treated for 10 min with 0.25 M HCl before denaturation with 0.5 M NaOH, neutralization and transfer to nitrocellulose filters $^{32.33}$. The transferred DNA was hybridized to a 32 P-nick-translated probe of a pBR322 recombinant plasmid containing the ~ 500 -bp coding region of the H1 histone gene of the h22 repeat (as constructed and provided by M. Busslinger). Autoradiography was performed with an intensifier screen at ~ 70 °C (panel b). Lane 1 is a control sample taken from the loaded injection needle before egg injection and represents the amount of DNA injected per egg. Lanes 2-6 represent nucleic acid samples prepared from egg/embryos at various developmental stages following DNA injection, and lanes 7-10 represent similarly prepared samples from uninjected embryos: lanes 2, 2, stage 2 (late blastula); lanes 2, 2, stages 2 (early tail-bud); lanes 2, 2, stages 2 (late blastula); lane 2, stages 2

tail-bud stage following injection of circular DNA (Fig. 2, lane 5).

The results of these experiments also show that the physical form of the injected DNA sequences changes dramatically during the early stages of development, extending the previous observation that linear DNA molecules rapidly ligate and concatemerize after injection into unfertilized eggs²⁴. This same ligation phenomenon seems to be occurring after the injection of the 6-kb linear sea urchin histone DNA into fertilized eggs.

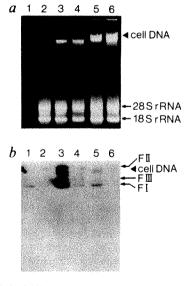

Fig. 2 Analysis by DNA blotting of the persistence and physical state of injected DNA sequences in developing embryos of X. laevis after the injection of fertilized eggs with supercoiled circles of sea urchin histone plus plasmid DNA. Circular, supercoiled pBR322 plasmid DNA containing two tandem copies of the h22 6-kb HindIII fragment was purified by CsCl gradient centrifugation and used to injected fertilized eggs. The injection procedure and subsequent analysis of embryonic nucleic acids were as described for injection of lines. DNA molecules (Fig. 1). Again, a is the ethidium-stained gel and b the corresponding autoradiograph. As in Fig. 1, lane 1 is a control sample representing the amount of DNA injected per egg (250 pg). Lanes 2-6 represent one embryo equivalent of nucleic acid extracted at stage 1 (egg), stage 8 (blastula), stages 10-12 (gastrula), stage 22 (early tail-bud) and stage 40 (swimming tadpole), respectively.

Thus, by late blastula, most of the hybridizable sequences co-migrate with high-molecular-weight cell DNA rather than as 6-kb linear DNA molecules (Fig. 1, lane 3). Together, these results suggest that after injection into fertilized eggs, linear DNA molecules ligate and then replicate in the developing embryos as high-molecular-weight concatemers.

However, supercoiled, circular (FI) DNA injected into eggs is processed differently. Previous work has shown that when SV40 FI DNA is injected into oocyte nuclei, the FI DNA is first relaxed but within 10 h re-acquires a supercoiled structure²⁵. Figure 2, lane 2, illustrates that immediately following injection of FI DNA into fertilized eggs at least half of the injected FI DNA is relaxed. By the blastula stage, there has been a large increase in the total amount of injected DNA sequences per embryo, and most appear as FI DNA (Fig. 2, lane 3). Thus, relaxed DNA seems to be converted back to FI DNA and replicates as such. After injection of either linear or circular sea urchin DNA, at least some of the injected DNA sequences persist as DNA co-migrating with high-molecular-weight cell DNA (Fig. 1, lanes 5, 6; Fig. 2, lane 5). Although there is no direct evidence that any of the injected DNA sequences have become integrated into the Xenopus genome, this notion is supported, at least for a minor fraction of the injected DNA sequences, by the persistence of some of the sequences to later stages in the high-molecular-weight range.

Having determined that the microinjected sea urchin histone genes persist in the Xenopus embryos, at least during early development, the next question was whether they were also faithfully transcribed, as judged by S₁ mapping of mRNA termini²⁶. As the injected gene copy number is highest at about the late blastula stage, the initial experiments examined RNA from this stage. S₁ mapping experiments were performed using a multiple probe capable of detecting simultaneously all five sea urchin histone mRNA 5' termini. As shown in Fig. 3, lanes 2-4, three bands co-migrating with the 5'-terminal sequences of the authentic H2B, H2A and H3 mRNAs are clearly visible. There is a faint band corresponding to the 5'-terminal sequence of H1 mRNA, but no band corresponding to the protected 5'-terminal sequence of H4 mRNA was detected. Controls with RNA from uninjected Xenopus embryos show no bands of protected sequences (Fig. 3, lane 5). This pattern of S₁ protection is

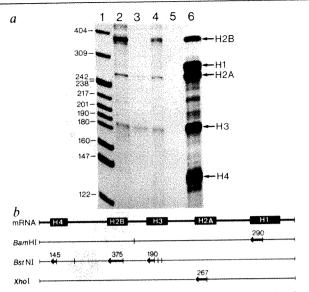

Fig. 3 Analysis by S₁ mapping of 5-14S RNA from Xenopus blastulae injected as eggs with sea urchin histone DNA. Artificially fertilized Xenopus eggs were injected with sea urchin histone DNA in either the linear or circular form as described in Figs 1 and 2 legends. Sucrose gradient-purified 5-14S RNA from the equivalent of 3.5 embryos (stage 9, late blastulae) was hybridized to a 32P-5'-end-labelled probe of triple-digested (BamHI-BstNI-Xhol) 6-kb h22 DNA. As illustrated in panel b, this multiple probe is capable of protecting the 5' termini of all five sea urchin histone mRNAs from S₁ digestion'. S₁ mapping was performed as previously described^{7,26,34}. Lane 1 is a size marker of ³²P-5'-end-labelled *Hpa*II fragments of pBR322. Lanes 2-4 are RNA samples from injected embryos; lanes 2 and 4 were injected with linear DNA molecules, lane 3 with the circular form. Lane 5 is RNA prepared in parallel from uninjected embryos. Lane 6 is 5 µg of total RNA from P. miliaris embryos at the 128-cell stage of development.

identical to that previously established for transcription in the oocyte7, suggesting that the same factors are governing the production and accumulation of the mRNAs and that no developmental change has occurred. Interestingly, both the injection of circular and linear DNA templates gave this pattern although, as discussed above, the actual templates in the blastulae were probably either circles or high-molecular-weight concatemers; moreover, the circles contained DNA sequences from the plasmid vector pBR322. These results suggest that the transcriptional pattern is a fundamental reflection of the relative efficiency of the individual sea urchin histone promoter sequences within the Xenopus transcriptional machinery.

RNA from injected blastulae was also analysed for transcripts with the correct 3' termini. The 3'-terminal sequences of the Psammechinus miliaris H2B, H3, H2A and H1 histone mRNAs can be detected using an S₁ mapping multiple probe of ³²P-3'end-labelled HpaII-XhoI restriction fragments of h22 (ref. 7). Bands of protected fragments co-migrating with the protected 3'-terminal sequences of authentic H2B and H2A mRNAs were visible (not shown), but the correct 3'-terminal sequences of the H3 and H1 mRNAs were not detected. With either the 5'- or 3'-multiple probe, RNA from the injected embryos gave numerous faint bands of unknown protected sequences, indicating that although at least some of the correct 5' and 3'termini are synthesized, there is also some incorrect transcription.

RNA samples from progressive stages of development (from immediately following injection of the fertilized egg to the swimming tadpole stage) were also examined. The transcriptional expression pattern was found to be quite similar at all stages, with the overall level of sea urchin histone gene transcription apparently governed only by the abundance of the injected gene sequences rather than by the developmental stage of the Xenopus embryo. This result is not unexpected because genes from a heterologous source would probably not be expected to be brought under Xenopus developmental control. For example, adult rabbit β -globin gene was also found to be expressed in Xenopus embryos using the same microinjection protocol²⁷. Also, as has recently been shown for the 5S rRNA genes²⁸, it is questionable whether naked DNA, even in a homologous system, respects developmental signals. Nevertheless, the approach described here paves the way for an assay capable of investigating what the units responding to developmental signals actually are and whether, for example, integration of genes into the correct chromosomal location is necessary before such signals are effective.

I thank S. Rusconi and C. C. Hentschel for assistance in egg injection and S1 mapping, C. C. Hentschel, W. Schaffner and M. L. Birnstiel for critical reading of the manuscript, and S. Oberholzer and F. Ochsenbein for help in preparing the manuscript. This work was supported by a Swiss Nationalfonds fellowship to M.M.B. under the sponsorship of M. L. Birnstiel and W. Schaffner.

Preferential adhesion of tectal membranes to anterior embryonic chick retina neurites

Willi Halfter, Michael Claviez & Uli Schwarz

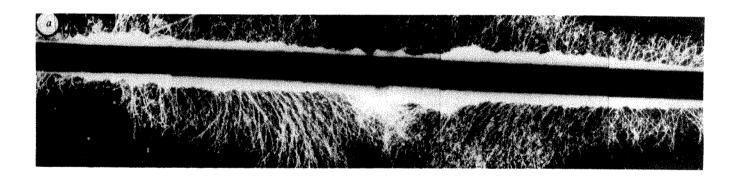

Max-Planck-Institut für Virusforschung, Abt. Biochemie, D-7400 Tübingen, FRG

Recognition between cells during embryogenesis is essential for the formation of precisely patterned neuronal networks such as the projection of axons from the retina on to the tectum in the avian optical system. A gradient of adhesion between retinal and tectal cells has been detected, with cells from the dorsal area of the neural retina adhering preferentially to cells of the ventral half of the visual tecta and vice versa (for review see ref. 1). This has supported the idea that topological relationships between cells are established through markers on the cell surface2. Such findings are based on adhesion between cell bodies, whereas it is only the axon tip of the retina ganglion cell which makes contact with and presumably recognizes tectal cells. Here, we have used a system in which outgrowing neurites from the retina were exposed to tectal cell surfaces in vitro and found a striking antero-posterior polarity in the chick retina.

Fig. 1 Adhesion of tectal membranes to neurites from anterior and posterior retina explants. A retina from a 6-day White Leghorn chick embryo was isolated. Squares (150×150 μ m) from the anterior and posterior region were explanted on a collagen-coated dish (Falcon 30001 F) and incubated at 37 °C in 4% CO2 for 2 days (2 ml of Eagle's minimal essential medium with 2.4% NaHCO₃ and 5 mM HEPES, 10% fetal calf serum, 2% chick serum, 1% beef embryo extract, 2 mM glutamine, penicillin and streptomycin; all from Gibco). Finally, 30 µl of a suspension of tectal membranes (see below; 150-200 µg protein)^{10,11} were added and incubation continued for another 2 h with gentle shaking at 30-min intervals. The medium was sucked off, the dish washed six times with prewarmed medium and the cultures were stained with Sudan black by a modification of the method of Wood¹² (after fixation with 2.5% glutaraldehyde in phosphatebuffered saline, impregnation in 0.19% OsO₄ and 0.5% K₂Cr₂O₇). Coating of the dish with collagen: native collagen was prepared essentially according to Elsdale and Bard¹³ (final concentration 350 μg ml⁻¹). At the onset of gelling, the dish was turned into a vertical position leaving a thin layer of collagen. The membranes were prepared by a modification of the procedure of Brunette and Till¹⁴. Tecta from 20 9-day-old chick embryos were homogenized in 4 ml of 10 mM Tris, 1.5 mM CaCl₂ and 1 mM spermidine (pH 7.4) in a Dounce homogenizer. After centrifugation (10 min at 1,000g) membranes were enriched in a biphasic system: a solution of dextran (13.1g dextran T-500, Pharmacia, in 67.8 ml H₂O bidest.) and a solution of polyethylene glycol 6000 (Carbowax, 8.95g, in 67.8 ml $\rm H_2O$ bidest.) were heated for 20 min at 80 °C, cooled and added to a solution of NaCl (15 mg NaCl in 113.4 ml 0.22 M Na-phosphate buffer, pH 7.0). After shaking and standing for 2 days at 4 °C, two phases had formed. The upper phase (polyethylene glycol) and lower (dextran) phases were separated and sterilized by membrane filtration. The membranes were homogenized in 5 ml of the polyethylene glycol solution and 5 ml of the

dextran phase was added. The two phases were mixed and centrifuged in a swing-out rotor for 10 min at 1,000g. Membranes from the interphase were resuspended in 4 ml polyethylene glycol. After addition of 4 ml dextran phase and mixing, separation was repeated by centrifugation for 10 min at 23,500g in a Sorvall HB4 rotor. The membranes were again collected at the interphase and washed twice in culture medium. Based on the specific activity of marker enzymes $^3 \text{ (Mg}^{2+}\text{-ATPase, NA}^+ - \text{K}^+\text{-ATPase}$ and alkaline phosphatase), the membranes were enriched by a factor of four over the homogenate. The recovery of alkaline phosphatase in the membrane was 30% of the enzyme activity found in unfractionated homogenate. a, Explants from the anterior half of the retina (right) and from the posterior half of the retina (left) grown on the same culture dish; b, c, explants at higher magnification.

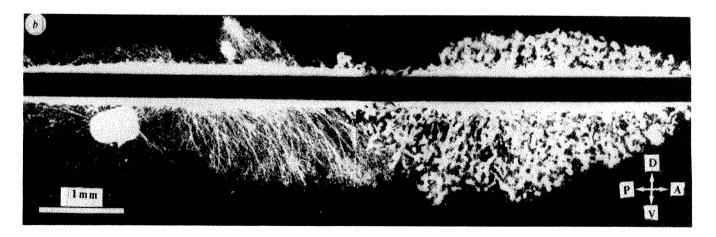

Fig. 2 Adhesion of tectal membranes to antero-posterior strips from the dorsal retina. A retina from a 6-day-old White Leghorn chick embryo was isolated intact and spread on a membrane filter (SM 13006, black; Sartorious); the ganglion cell layer was oriented upwards. The retina and membrane filter were cut into 0.3-mm strips in the antero-posterior direction, inverted on to collagen-coated dishes, and cultured as before, the ganglion cell layer now facing the collagen (Fig. 1), with the exception that a thicker collagen layer was used (0.7 ml collagen solution was allowed to form a gel in Petriperm dishes; Heraeus). After incubation for 30 h, a suspension of tectal membranes (see Fig. 1) was added. After incubation for 2 the unbound membranes were washed off (see Fig. 1) and the specimen observed directly by dark-field illumination. a Is a control without membranes added, showing the oriented outgrowth of fibres towards the original choroid fissure which is oriented vertically through the centre of the strip; b shows the specific adhesion of tectal membranes to the neurites sprouting from the anterior half of the retina. The original orientation of the retina in the embryo is indicated by the windrose (D, dorsal; A, anterior, V, ventral; P, posterior).

Retina from 6-day chick embryos, when explanted and incubated on collagen, shows vigorous fibre growth. Using the choroid fissure as a topographical marker, small pieces of retina from defined regions were explanted. After 2 days in culture, a suspension of tectal cells, isolated by mechanical dissociation, was added and the incubation continued for a further 2 h with gentle shaking at 30-min intervals. Finally, the culture was washed and observed by dark-field illumination. In these experiments, preferential adhesion of tectal cells to neurites growing out from anterior retinal explants was observed. However, clarity of the results was impaired by the fact that the cells adhered to collagen and also to each other (data not shown). A much sharper distinction was obtained using membrane preparations from tectal cells, instead of whole cells. A striking preferential adhesion of tectal membranes to neurites from explants of anterior retina, as opposed to neurites growing out from posterior sections, was observed (Fig. 1). Identical results were obtained with membranes prepared by the elaborate procedure of Merrell and Glaser³

The specific adhesion of tectal membranes to anterior neurites could reflect a continuous gradient or a discontinuous step of adhesiveness in the antero-posterior dimension of the retina. To decide on this alternative the retina was spread on a membrane filter and cut into narrow strips with a tissue chopper. The retinal strips were transferred on to collagen with the filter as a mechanical support. Using the choroid fissure for orientation, strips were cut in antero-posterior and in dorso-ventral directions. Such explants produced neurites in vitro. In agreement with results reported by Bonhoeffer and Huf4, their orientation is similar to that of axons in vivo5, that is, neurites grew centripetally towards the original position of the choroid fissure (Fig. 2a). Antero-posterior strips were explanted and incubated for 30 h and the adhesion of tectal membranes to the neurites was then tested as before. Microscopic examination showed very clearly two distinct areas with a sharp boundary; neurites from the anterior part of the retina were heavily labelled with

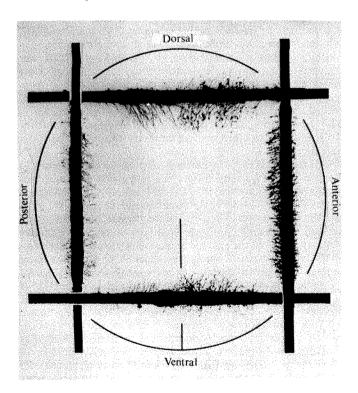

Fig. 3 Composite of four photographs taken from strips of the retina cut as indicated, explanted, incubated and treated with tectal membranes as described (Fig. 2). The antero-posterior sections from the dorsal and ventral parts of the retina came from one retina; the other two sections from another retina of a 6-day-old chick embryo. The samples were stained with Sudan black (Fig. 1) before photography. Over 200 experiments yielded identical results. The vertical line indicates the position of the choroid fissure; the strips are 0.3 mm wide.

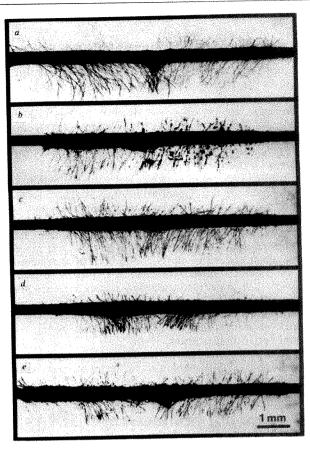

Fig. 4 Adhesion of membranes of different origin to neurites sprouting from antero-posterior sections through chick retina. The retina sections were prepared and incubated as described. After incubation for 30 h, membrane preparations from different parts of the central nervous system were prepared and the samples processed as described in Fig. 1 legend. a, Untreated control; the remaining preparations were treated with: b, membranes from optic tectum; c, membranes from brain prepared after removal of the optic tectum; d, membranes from retina and e, from forebrain. The membranes had all been prepared from 9-day-old White Leghorn chick embryos.

membranes, in contrast to the posterior fibres (Fig. 2b). The neurites from dorso-ventral strips through the anterior part of the retina were covered with large amounts of membrane material whereas on dorso-ventral strips through the posterior part of the retina much less membrane material was bound. Only by scanning electron micrography could membrane vesicles be detected on posterior neurites. A composite of photographs taken from four sections through the anterior, ventral, posterior and dorsal regions of the retina indicates the distinctive adhesion of tectal membranes to neurites originating from the anterior half of the retina, independently of the dorso-ventral coordinate (Fig. 3). All results indicate that neurites from the anterior and posterior part of the retina differ strikingly in binding tectal membranes. A similar antero-posterior polarity in retina can also be seen after a modification of the test system4 in which neurites growing out on cell monolayers can choose between retina and tectum cells; anterior neurites prefer tectum cells, posterior neurites do not (F. Bonhoeffer, personal com-

The sprouting of neurites from retina explants reflects the time course of axon outgrowth in vivo⁵, which occurs between days 5 and 8. All stages within this range showed the specific binding of tectal membranes to anterior neurites. The age of the tectum used for membrane preparation was not relevant for adhesion; membranes from 6-13-day-old embryos all showed adhesion to anterior neurites. Retinal axons do not reach the tectum until day 6 of development⁶⁻⁸, indicating that the neurites do not recognize retina-derived components on the tectum. It remains to be studied whether the neurites in vitro are true axons which originate mainly from ganglion cells, and whether they grow out de novo or are due to

regeneration. However, fibre orientation, time of outgrowth and the agreement between the number of ganglion cells in our explants and the number of fibres (M.C., in preparation), are consistent with a ganglion cell origin.

The origin of the membranes is crucial for the recognition by neurites. In contrast to the membranes from the optic tectum. membranes from fore-brain were not bound to anterior neurites in a selective manner (Fig. 4). However, a slight general adhesiveness of these membrane preparations to the neurites was observed (Fig. 4c-e). Membranes from non-neural tissue such as liver also showed some adhesion to all neurites with no preference for the anterior part.

The adhesion of membranes was not inhibited by blocking protein synthesis in the explant with cycloheximide (5 µg ml⁻¹) before and during incubation with the membranes. Similarly, the addition of concanavalin A (2.5 µg ml⁻¹) and colchicine (12.5 ng ml⁻¹) showed no effect at concentrations which interfered with further neurite elongation. However, fixation with glutaraldehyde and, interestingly, the addition of cytochalasin B (5 µg ml⁻¹) blocked membrane-binding. Cytochalasin B has a specific effect on growth cone activity9, causing a retraction and wilting of the microspikes, by which the axonal environment is explored. Intact function of growth cones, therefore, might be essential for the recognition and/or adhesion of the tectal membranes to retinal neurites.

The antero-posterior polarity as we found it in vitro might be involved in the establishment of retino-tectal connections dur-

ing in vivo development; this assumption, however, requires further study. In any case, the findings clearly show that the retina consists of subareas distinguishable by their interactions with tectal membranes; they provide a relatively simple assay for further studies of this interaction. For example, we can test whether the antero-posterior polarity in the retina has a counterpart in the tectum. Furthermore, a biochemical characterization of the components involved in the interaction of the neurites with the tectal membranes should be possible.

We thank Dr Dütting for advice on tissue culture, F. Bonhoeffer, A. Gierer, D. Dütting for helpful discussions and D. Newgreen for suggestions in preparing the manuscript.

One gene, but two messenger RNAs encode liver L and red cell L' pyruvate kinase subunits

Joelle Marie, Marie-Pierre Simon, Jean-Claude Dreyfus & Axel Kahn

Institut de Pathologie Moléculaire, INSERM U 129, Chu Cochin 75674 Paris Cedex 14, France

Pyruvate kinase subunits of red cells and liver differ in their molecular weights. Peptide mapping of the rat enzymes has shown that this difference is due to a single exon peptide present in the red cell enzyme¹⁻³. There is strong genetic evidence in man that both enzymes are encoded by the same structural gene (refs 4-8 and G. E. J. Staal et al., personal communication). Here we describe in vitro protein synthesis experiments using RNA extracted from rat red cells and liver which demonstrate that the difference is reflected in tissue-specific mRNAs. Thus the difference is not due to post-translational processing and presumably involves either gene rearrangement or differential processing of a common nuclear RNA precursor.

In our laboratory, we have demonstrated that pyruvate kinase is synthesized in red cells as L' subunits $(M_r 63,000)$ and in liver as L subunits (M_r 60,000). In vitro, the L'₄ tetramers can be converted by mild tryptic attack into a form with molecular weight and properties similar to liver L_4 pyruvate kinase⁹⁻¹². As both trypsin-treated red cell enzyme and liver pyruvate kinase exhibit improved regulatory properties with respect to native L'4 (refs 9, 12), it was assumed that, in liver, L-type pyruvate kinase undergoes a proteolytic processing. To test this model we have characterized pyruvate kinase neosynthesized in a rabbit reticulocyte lysate system under the direction of human liver RNA, rat liver RNA or rat reticulocyte RNA. If the L and L' subunits differ due to a proteolytic processing, then reticulocyte and liver RNAs should direct the synthesis of identical subunits with an identical molecular weight to L'.

Anti-human red cell pyruvate kinase antiserum was raised in rabbits and specific antibodies purified by chromatography on a pyruvate kinase-linked agarose bead column¹³. The purified

antibodies were then coupled to agarose beads. By exploiting the cross-reactivity between human and rat enzymes, it was possible, using this immunoabsorbent, to purify pyruvate kinase from human liver, rat liver and rat red cells in only one step (Fig. 1). Rat L' and L subunits were slightly heavier than their human counterparts (Mrs 64,000 and 61,000 respectively). Reticulocytosis was induced in rats by treatment with acetylphenylhydrazine¹⁴. Total cellular high-molecular-weight RNA was purified by ethanol precipitation in 7 M guanidine/HCl solution followed by chloroform/isoamyl alcohol extraction and washing in 3 M sodium acetate 13,15. Reticulocyte RNA was fractionated by two successive centrifugations on denaturing methylmercury/formamide gradients. The fractions corresponding to sedimentation coefficients 18S-~24S were pooled and, after ethanol precipitation, RNA was used for in vitro translation. Total cellular high-molecular-weight liver RNA was used to direct protein synthesis without further fractionation.

Cell-free synthesis was performed, in some experiments, in the presence of various antiproteolytic agents: 0.01 mM leupeptin, 0.1 mM chymostatin, 0.1 mM antipain, 0.1 mM pepstatin, 0.1 mM diisopropylphosphofluoridate and 1% (v/v)aprotinin. Neosynthesized pyruvate kinase subunits were purified by immunoaffinity chromatography on microcolumns containing 5 µl of the specific immunoabsorbents¹³. Specificity of the neosynthesized bands was checked by immunological competition with unlabelled L-type pyruvate kinase¹³. Figure 2 shows that rat liver RNA directed synthesis of a polypeptide of M_r 61,000—the same molecular weight as rat liver L-type pyruvate kinase. This molecular weight was the same whether cell-free translation was performed with or without antiproteolytic agents. This polypeptide could be firmly identified as neosynthesized pyruvate kinase because it did not bind to an antipyruvate kinase-agarose column previously saturated with excess unlabelled L-type enzyme but was specifically retained by a nonsaturated column (Fig. 3). The same results were obtained with human liver RNA (not shown).

Figure 4 shows that, by contrast, rat reticulocyte RNA directed synthesis of a $64,000-M_r$ polypeptide (thus similar to rat L') which immunologically competed with unlabelled L-type enzyme for binding to the antibody column. When a mixture of reticulocyte and liver RNAs was translated together, both the

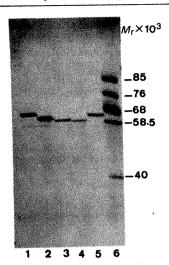

Fig. 1 Purification of red cell and liver pyruvate kinase from man and rat by immunoaffinity microchromatography. Cells or tissues were lysed in a 50 mM Tris-HCl buffer (pH 7.4) containing 150 mM NaCl, 0.1 mM β-mercaptoethanol, 10 mM EDTA, 10 mM ε-aminocaproic acid, 2% (v/v) aprotinin, 1 mM diisopropylphosphofluoridate, 0.1 mM pepstatin, 0.1 mM chymostatin, 0.1 mM antipain, 0.01 mM leupeptin, 1% (v/v) Triton X-100, 1% (w/v) sodium deoxycholate (= lysis buffer). After elimination of the insoluble cell debris by centrifugation (at 36,000 g for 20 min), the extracts were applied to microcolumns made with Eppendorf blue tips and containing 10 µl of immunoabsorbent (4 mg of specific anti-L-type pyruvate kinase immunoglobulins per ml of resin). About 3 IU of pyruvate kinase were bound per column. The columns were washed successively with 5 ml of lysis buffer, 5 ml of 0.1 M sodium phosphate buffer (pH 7.4) containing 1 M KCl and 5 ml of 0.1 M sodium phosphate buffer (pH 7.4) containing 0.15 M NaCl. They were eluted with 800 µl of 0.1% (w/v) SDS in 10% (v/v) acetic acid. The eluates were lyophilized and the lyophilisates dissolved in 40 µl of 0.0685 mM Tris/HCl buffer (pH 6.8) containing 10% glycerol (v/v)5% β -mercaptoethanol (v/v) and 0.0 01% bromophenol blue (w/v); dodecylsulphate concentration of these samples was therefore 2% (w/v), such that they could be directly applied, after dissociation (2 min in boiling water), to dodecylsulphate/polyacrylamide gradient gel electrophoresis according to Laemmli²⁷. Proteins were stained with Coomassie brilliant blue. 1, rat red cell; 2, rat liver; 3, human liver; 4, trypsin-treated human red cell enzyme⁹; 5, untreated human red cell enzyme; 6, protein markers: urease (Mr 85,000), transferrin (76,000), bovine serum albumin (68,000), glucose phosphate isomerase (58,500) and half urease (40,000). The faint band corresponding to a M_r of $\sim 57,500$ observed in the pyruvate kinase preparations corresponds to Lc, a partially proteolysed form

61,000 and 64,000 bands could be detected (not shown). This result, and the fact that antiproteolytic agents did not modify the molecular weight of neosynthesized liver pyruvate kinase, exclude the possibility that neosynthesized chains are cleaved by proteases present in the reticulocyte lysate or by neosynthesized proteases. Clearly, therefore, in rat, L and L' pyruvate kinase subunits are synthesized under the direction of two different species of mRNA. Although it was not possible to study human reticulocyte RNA, the same conclusion can probably be drawn in man because human liver RNA directs synthesis of L, and not L' as predicted by the hypothesis of the 'proteolytic processing'.

As studies of inherited red cell pyruvate kinase deficiency indicate unambiguously that L and L' subunits are encoded by the same gene, our results strongly suggest that this gene is associated with two types of mRNA present in the different cells—erythroid and liver. Two basic mechanisms could explain this finding: a rearrangement of the L-type pyruvate kinase gene during erythroid or liver differentiation, or a differential processing of a common nuclear RNA precursor.

In lower eukaryotes, a gene rearrangement mechanism has been implicated, such as in the yeast mating system 16,17 and modification of trypanosome surface antigens 18.

In vertebrates, gene rearrangement has been described only for immunoglobulin genes during B-cell differentiation19 Differential processing of nuclear RNA has been described for immunoglobulin μ chains²²⁻²⁴, where both types of μ chain, and therefore both types of mRNA, are produced in the same cells, whereas in the case of pyruvate kinase, L' is the only form produced in the reticulocytes and L the only form in the liver. Differential splicing of nuclear RNA in salivary glands and liver 25,26 has also been shown for mouse α -amylase; in this case the two species of mRNA encode the same protein. These results suggest that differentiation can be associated with changes of protein form that are not directly related to the usual phenomena of gene activation and inactivation, but rather to modifications of gene arrangement or of processing of nuclear RNA into cytoplas mic translatable mRNA. The study of pyruvate kinase genomic DNA in different cells should elucidate this problem, but requires a cDNA probe which may be difficult to obtain because of the very low amount of specific mRNA:

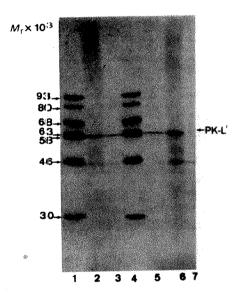

Fig. 2 Characterization of neosynthesized liver L-type pyruvate kinase subunits. Rabbit reticulocyte lysate was deprived of endogenous RNA by micrococcal nuclease treatment, according to ref. 28. Translation mixture (250 µl) contained, in final concentration, 20 μM essential amino acids except methionine, 0.5 mCi ³⁵Smethionine (specific activity 1,000 Ci mmol-1), 1 mM ATP, 0.2 mM GTP, 0.3 mM spermidine, 1 mM dithiothreitol, 10 µM haemin, 10 mM creatine phosphate, 60 µg ml⁻¹ creatine phosphokinase, 20 mM HEPES buffer, pH 7.4, 120 mM K acetate, 1.20 mM Mg a cetate and 40 µg liver RNA. Translation was carried out for 1 h at 37 °C, then the reaction was diluted with 2 vol of the 'lysis buffer' described in Fig. 1 legend and centrifuged at 36,000 g for 30 min. The diluted translation mixture was applied to two combined microcolumns (inserted into each other), containing 10 μ l nonimmune γ -globulin-linked resin at the top and 5 μ l anti-pyruvate: kinase resin at the bottom. After about six passages through this system, the microcolumns were separated, individually washed and eluted as described in Fig. 1 legend. Lanes 1 and 4, C-labelled protein markers: rabbit muscle phosphorylase (M, 93,000), human muscle phosphofructokinase (M_r 80,000), bovine serum albumin (M, 68,000), human L'4 red cell pyruvate kinase $(M_r 63,000)$, human glucose phosphate isomerase $(M_r 58,500)$, hen egg ovalbumin (M, 46,000) and bovine carbonic anhydrase (M_r 30,000). Lanes 2 and 6, eluates from anti-pyruvate kinase columns, synthesis without addition of antiproteolytic agents. 3 and 5, eluates from anti-pyruvate kinase columns, synthesis in the presence of 0.01 mM leupeptin, 0.1 mM pepstatin, 0.1 mM chymostatin, 0.1 mM antipaīn, 0.1 mM diisopropylphospho-fluoridate, 1% (v/v) aprotinin. 7, eluate from a nonimmune column. The $43,000-M_r$ band, observed in the eluates from nonimmune systems as well as from some specific immuno-absorbent columns, can be identified as contaminant actin 13. Fluorography was performed as in refs 29 and 30.

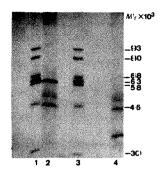

Fig. 3 Characterization of neosynthesized liver L-type pyruvate kinase by immunological competition. Cell-free translation was carried out as indicated in Fig. 2 legend, but the reaction was passed, successively, through saturated and nonsaturated antipyruvate kinase resins. The immunoabsorbent was saturated with 100 µg cold human L-type enzyme, then the res in was extensively washed before being used with the neosynthesized products. Lanes 1 and 3, ¹⁴C-labelled protein markers (as in Fig. 2 legend). 2, eluate ⁴C-labelled protein markers (as in Fig. 2 legend). 2, eluate from a 5-µl nonsaturated anti-pyruvate kinase column. 4, eluate from 5-µl saturated anti-pyruvate kinase column. Detection of the radioactive bands by fluorograph v.

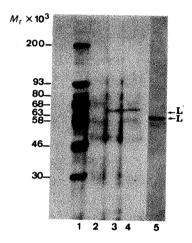

Fig. 4 Characterization of neosynthesized L' red cell pyruvate kinase by immunological competition. Comparison with neosynthesized L enzyme. Cell-free synthesis was directed by fractionated 18S-24S reticulocyte RNA (30 µg per 250 µl of translation medium) (lanes 2-4) or by rat liver RNA, as indicated in Fig. 2 legend (lane 5).

Fractionation of reticulocyte RNA was carried out by centrifugation in denaturing methylmercury formamide/sucrose gradient. 400 µg RNA were first dissolved in 20 µl 10 mM methylmercury, incubated at room temperature for 5 min, then mixed with 200 µl of 90% deionized formamide (v/v) in 10 mM Tris-HCl, pH 7.5, 10 mM iodoacetate, 5 mM EDTA and 0.5% lauroyl sarcosine. After a 15-min incubation at room temperature, this RNA solution was diluted with 250 µl of the Tris-HCl buffer described above, but without formamide, and applied to an 11-ml gradient sucrose: 10-25% (w/v) sucrose in 10 mM Trisi-HCl, pH 7, containing 50% (v/v) deionized formamide, 10 mM iodoacetate, 5 mM EDTA and 0.5% (w/v) lauroyl sarcosine. Centrifugation was carried out in a SW 41 Beckman rotor, at 40,000 r.p.m. for 14 h. The 18S-24S RNA was pooled and precipitated by ethanol, and then applied to a second gradient. The 18S-2:4S fraction obtained from the second round was used for directing cell-free

translation.

Lane 1, 14 C-labelled protein markers: myosin (M_r 200,000), phosphorylase, muscle phosphofructokinase, bovine serum albumin, L' human pyruvate kinase, glucose phosphate isomerase, ovalbumin, carbonic anhydrase and lactoglobulin A $(M_r 18,500)$. Lane 2, synthesis directed by reticulocyte RNA, eluate from a 5-µl saturated anti-pyruvate kinase column. Lanes 3 and 4, synthesis directed by reticulocyte RNA; eluates from 5-µl nonsaturated anti-pyruvate kinase columns. Lane 5, synthesis directed by liver RNA, eluate from 5-µl nonsaturated anti-pyruvate kinase column. Detection by fluorography.

pyruvate kinase represents < 0.05% of the proteins synthesized under the direction of liver RNA in cell-free conditions and this proportion is even less for reticulocyte RNA.

This work was supported by INSERM grant CRL 80-1028. We thank Dr Jacques Kruh and Fanny Schapira for helpful discussion and advice, and F. Carrouget for typing the manu-

Note added in proof: We recently succeeded in translating in a cell-free system both L and L' messenger RNA from fetal human liver, which confirms that in man as well as in rat L and L' pyruvate kinase subunits are encoded by two different species of messenger RNAs.

Nucleotide sequence of the

haemagglutinin gene of a human influenza virus H1 subtype

Greg Winter*, Stan Fields* & George G. Brownlee†

*MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

†Sir William Dunn School of Pathology, University of Oxford. South Parks Road, Oxford OX1 3RE, UK

Influenza remains a serious cause of disease in man and of death in the aged. Vaccination is only transiently effective in providing immunity1, because the surface haemagglutinin molecule of the virus can evolve rapidly, allowing the virus to escape neutralization by immunizing antibody. Of the three influenza A subtypes² known to cause infection in man, the H1 subtype is of particular interest as it has proved to be the dominant human subtype this century and is now co-circulating with variants of the H3 subtype. Here we present the sequence of the haemagglutinin gene of an early H1 subtype (strain A/PR/8/34) as determined by recombinant DNA methods and dideoxy sequencing. From the deduced amino acid sequence of the haemagglutinin we define an antigenic site at amino acid residue 160. Comparison with haemagglutinin molecules³⁻⁹ shows that the H1 and H2 subtypes are more homologous to one another than to the other subtypes, which suggests that they have diverged only recently from one to another.

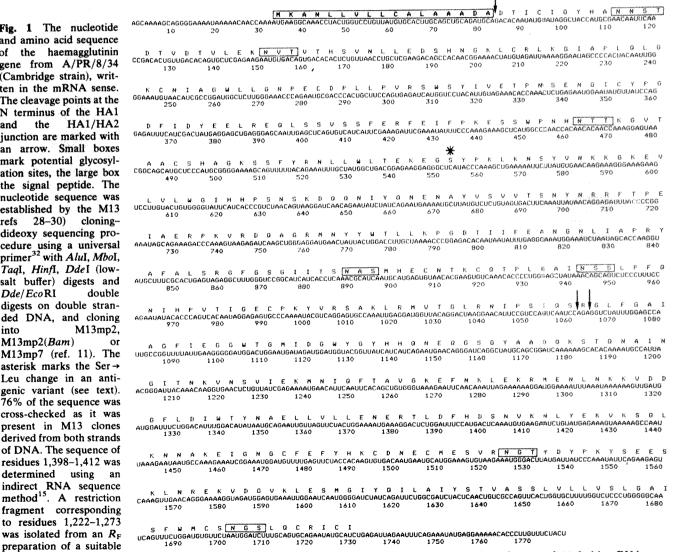

Influenza is a negative-stranded virus with eight RNA genes coding for 10 or more proteins, of which band 4 codes for the haemagglutinin gene. The main strategy for sequencing this gene was similar to that used in a parallel study of the neuraminidase gene 10-12. Briefly we prepared restriction fragments derived from double-stranded DNA, itself prepared by in vitro copying of the RNA gene 4 by reverse transcriptase. These restriction fragments were cloned into the bacteriophage M13 vector and sequenced by the Sanger method^{13,14}. By sequencing clones which were isolated at random and derived from several different restriction enzyme digests, we hoped to overlap these clones and deduce a unique sequence for the haemagglutinin gene. This objective was only 99% achieved; for the remaining 1% of the sequence we had to use an indirect RNA sequencing method¹⁵. We also used a direct RNA sequencing method to confirm the sequence of one end of the gene 16.

Figure 1 shows the deduced nucleotide sequence, written in the mRNA sense. Its organization is similar to haemagglutinin molecules previously studied in other subtypes^{3-9,17}. We can identify a 17-residue hydrophobic signal peptide, an HA1 subunit (326 residues long) and an HA2 subunit (222 residues long). These, as in the other human subtypes, are separated by a single arginine residue (327) which is presumably recognized during processing by a trypsin-like enzyme. The HA2 subunit contains the characteristic conserved 14-amino acid long hydrophobic N-terminal sequence as well as a hydrophobic tail, believed to anchor the molecule to the phospholipid bilayer of the cell18.

Our studies provided no direct information on the secondary structure of the haemagglutinin, but we can deduce from the conservation of cysteine residues (Fig. 2) that the pattern of disulphide bonds is probably similar to that of the H2 and H3 subtypes, where most cysteines are involved in S-S bridges within a subunit, except for C(14) and C(466) (see Fig. 2) which interconnect the separate subunits19. There is no information on the three conserved cysteine residues close to the C terminus of the HA2 subunit. The haemagglutinin is a glycoprotein in which we observe seven potential N-X-S or N-X-T sequences (Fig. 1) where carbohydrate could be attached²⁰. There have been no direct studies of the location of the carbohydrate in A/PR/8/34, but studies of related strains (A/WSN/33)21 and other subtypes (A/Japan/57)4 suggest that the majority are glycosylated. Presumably the most N-terminal glycosylation site in the HA1 subunit (N-N-S-T-a sequence also conserved in the H2 subtype) is glycosylated at one but not both of the asparagine residues4.

Monoclonal antibodies have been previously used to select A/PR/8/34 variants which escape antibody neutralization because of their altered antigenicity²². A common variant contained a leucine residue replacing a serine residue in the parental tryptic peptide (SEPGY)K, although this peptide could not be further localized within the sequence. From the amino acid sequence predicted here (Figs 1, 2), we identify this variant as serine → leucine (160) caused by a C → U transition at base 553. Residue 160 (for numbering of amino acids, see Fig. 2

Fig. 1 The nucleotide and amino acid sequence of the haemagglutinin gene from A/PR/8/34 (Cambridge strain), written in the mRNA sense. The cleavage points at the N terminus of the HA1 the HA1/HA2 junction are marked with an arrow. Small boxes mark potential glycosylation sites, the large box the signal peptide. The nucleotide sequence was established by the M13 refs 28-30) cloningdideoxy sequencing procedure using a universal primer³² with AluI, MboI, TaqI, HinfI, DdeI (lowsalt buffer) digests and Dde/EcoRI double digests on double stranded DNA, and cloning M13mp2, into M13mp2(Bam)M13mp7 (ref. 11). The asterisk marks the Ser→ Leu change in an antigenic variant (see text). 76% of the sequence was cross-checked as it was present in M13 clones derived from both strands of DNA. The sequence of residues 1,398-1,412 was determined using an indirect RNA sequence method¹⁵. A restriction fragment corresponding to residues 1.222-1.273 was isolated from an R_F

recombinant haemagglutinin clone and was used as a primer for dideoxy sequencing using reverse transcriptase and total virion RNA as template ¹⁰. The 5' end of band 4 virian RNA was checked by direct RNA sequencing ¹⁶. The computer programs of Staden ³¹ were used to assist data handling and overlapping of fragments.

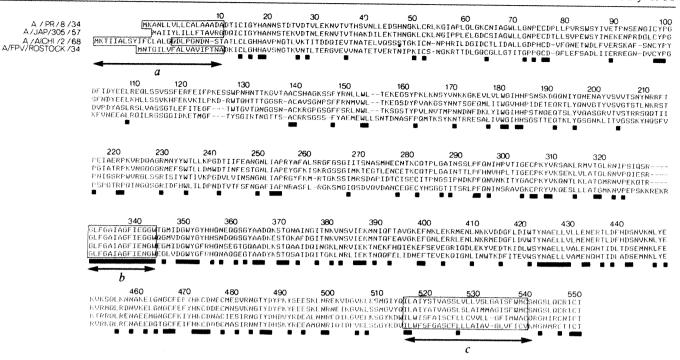

Fig. 2 The amino acid sequences of haemagglutinin from A/PR/8/34 (H1 subtype), A/Jap/305/57 (H2 subtype), A/Aichi/2/68 (H3 subtype) and A/FPV/Rostock/34 (H7 subtype) are listed with gaps inserted generally to maximize amino acid homology and particularly the alignment of cysteine, tryptophan and proline residues. The precise position of gaps is rather subjective but was finally decided after inspection of the three-dimensional structure of the H3 subtype. Saps were then introduced into regions which, by analogy with the H3 subtype, might be expected to be in surface loops. The numbering system is based on consecutive amino acid residues (ignoring gaps) starting at the terminus of the H3 subtype (A/Aichi/2/68). Thus residue 160 of A/PR/8/34 is actually residue 157 from its N terminus, but is homologous to 160 of A/Aichi/2/68. The boxed areas a, b and c mark, respectively, the signal peptide region, the conserved N terminus of the HA1 subunit and the membrane attachment C-terminal tail.

legend) has not previously been implicated as an antigenic site in the better studied H3 subtype, despite the fact that the homologous residue threonine (160) seems to be on the surface of the haemagglutinin in the proposed site B in the recently available three-dimensional model of the H3 subtype²³. Perhaps the presence of the nearby carbohydrate side chain at residue 165 masks this region in the H3 subtypes. Further studies of other laboratory variants as well as field strains with altered antigenicity are required to define the antigenic regions of the H1 subtype in more detail.

Figure 2 shows a comparison of the amino acid sequence of the A/PR/8/34 haemagglutinin with representative strains of three other subtypes. The fact that only occasional gaps were required in one or other of the sequences to maintain alignment confirms the basic homology of all haemagglutinin subtypes. Furthermore, the conservation of cysteine and many proline residues predicts a common overall shape. Table 1 gives a quantitative measure of the extent of amino acid and nucleotide similarity between the different subtypes. This clearly shows that the H1 and H2 subtypes are more closely related to one another in both their HA1 and HA2 subunits than either is to the H3 or

Table 1 Conservation of amino acid and nucleotide sequences in strains of different H subtypes

		% Amino acid conservation			
	H1	H2	Н3	H7	
H1		58(79)	35(53)	33(51)	
H2	61(72)		36(50)	35(53)	
H3	45(58)	45(57)		36(65)	
H7	44(58)	46(59)	45(66)		
	%	Nucleotide con	servation		

The conservation in the HA1 subunit is given first, with the conservation in the HA2 subunit shown in parentheses. Amino acid conservation is listed above the diagonal and nucleotide conservation below. See Fig. 1 legend for the specific strains used in this comparison.

H7 subtypes. The 58% amino acid conservation in the HA1 subunit of the H1 and H2 subtypes is far greater than the typical 33-36% similarity of the other possible comparisons. The fact that H1 and H2 subtypes are related is also apparent from the nucleotide sequence comparisons (Table 1).

The demonstrable homology of all haemagglutinin subtypes shows that they must have evolved from a common ancestral gene by a process of point mutation and the occasional deletion and addition. From the extent of antigenic drift in the human H3 subtypes, we know that change can occur quickly at a rate in the order of 1% amino acid change per year for the HA1 subunit (a value estimated from the extent of drift in the H3 series A/NT/60/68, A/Memphis/102/72 and A/Victoria/2/75)^{24,8} Thus, in theory, if this rate of drift were maintained and were also applicable to the H1 subtype, the 42% difference in the amino acid sequence of the HA1 subunit of the H1 and H2 subtypes could have arisen on the assumption that H2 evolved from the H1 subtype in a 42-yr period. But surveillance of human influenza strains since their isolation in 1933 (ref. 25) suggests that the H1 subtype did not undergo such an extensive 'drift', at least in man. No intermediate linking strains spanning the H1 and H2 subtypes were isolated; the H2 subtype appeared suddenly in 1957 (along with a new neuraminidase subtype) presumably from a mammal or bird reservoir in which influenza is common²⁶. There remains the possibility that drift of the H1 subtype giving rise to the H2 subtype occurred in a mammalian or avian reservoir. Indeed, H1 strains do infect pigs25 but again no evidence of intermediate strains between the H1 and H2 subtype have been observed in the last 48 yr.

Thus, the H1 and H2 subtypes are evolutionary more closely related to one another than either is to the H3 and H7 subtypes but the evolutionary time scale cannot yet be estimated. It will be interesting to sequence completely some of the eight other known mammalian or avian haemagglutinin molecules because distant relationships between subtypes could have remained undetected in the traditional immunological screening methods used to classify haemagglutinin subtypes². An independent

sequence analysis of the haemagglutinin of another H1 subtype, A/WSN/33, has recently been completed²⁷. This strain also shows homology to the H2 subtype.

We thank Mrs M. A. Robertson for supplying virus and RNA and Dr A. Caton for critical reading of the manuscript. G.G.B. is supported by a MRC project grant S.F. by a NSF predoctoral fellowship and G.W. by a research fellowship from Trinity College, Cambridge.

Note added in proof: We recently learnt of a Chinese report³³ providing serological evidence of shared antigenic determinants between late variants of the H1 subtype and early variants of the H2 subtype; this correlates well with their molecular homology.

The origins of replication of the yeast mitochondrial genome and the phenomenon of suppressivity

Miklos de Zamaroczy, Renzo Marotta, Godeleine Faugeron-Fonty, Regina Goursot, Marguerite Mangin, Giuseppe Baldacci & Giorgio Bernardi

Laboratoire de Génétique de Moléculaire, Institut de Recherche en Biologie Moléculaire, 2, Place Jussieu, 75005 Paris, France

The 'petite colonie' mutation of Saccharomyces cerevisiae1,2 is characterized by an irreversible loss of respiration and by an extraordinarily high spontaneous mutation rate^{3,4}. Crosses of wild-type cells with petite mutants exhibit a non-mendelian segregation of the mutation, yielding either wild-type progeny , or both wild-type and petite mutants in proportions essentially dependent on the particular petite used3. In the first case, the petites entering the cross are called neutral, in the second one suppressive³. While the molecular basis of the spontaneous petite mutation is now understood⁴⁻¹², suppressivity has remained an elusive phenomenon for the past 25 yr. We report here that the mitochondrial genome of most spontaneous petites (which is exclusively made up by the tandem repetition of a DNA segment excised from the genome of parental wild-type cells -8) carries at least one of the ori

sequences of the parental wild-type genome. These are long homologous DNA stretches showing striking similarities with the origins of replication of mitochondrial DNAs from mammalian cells. The properties (intact or altered primary structure, high or low number) of the ori sequences of petite genomes seem to determine suppressivity—the level of transmission of petite genomes to the progeny of crosses with wild-type cells. These results indicate that ori sequences are indeed origins of DNA replication and that suppressivity depends on the relative replication efficiencies of petite and wild-type genomes.

We previously proposed that the mitochondrial genome of wild-type yeast cells contains several origins of replication and that at least one of them is carried by the excised segment which will become the repeat unit of a spontaneous petite¹³. We tentatively localized such an ori sequence within the common central stretch of the genome of two spontaneous petites excised from the same region of the wild-type genome^{6,7}. This stretch is characterized (refs 7, 12 and Figs 1, 2, 4) by two short GC clusters, A and B, flanking a 23-nucleotide AT palindrome, p, and a short sequence, s; and by one long GC cluster, C, separated from B by long AT sequence, l. We then found a common 80-base pair sequence centred on cluster B, and more recently, the whole *ori* sequence in petite genomes derived from five regions of the wild-type genome 10-12,14,15.

Screening of the mitochondrial genomes of ~400 spontaneous petites derived from wild-type strain A⁵ revealed that all except two contained an ori sequence, as judged from the restriction sites located on clusters A, B and C (Fig. 1; Table 1). Restriction mapping showed that the eri sequences of different petite genomes were surrounded by different flanking regions and indicated the existence of at least seven ori sequences, ori 1-7 (Fig. 1), on the wild-type genome. This conclusion was confirmed by hybridization experiments in which labelled mitochondrial DNAs from petite genomes carrying different ori sequences showed seven common hybridization bands on HaeIII fragments from the parental wild-type genome; these fragments had the same sizes as HaeIII fragments carrying the different ori sequences on the petite genomes of Fig. 1. An eighth hybridization band might indicate the existence of yet another origin.

Figure 1 also shows that (1) three petite genomes, a-3/1/5/B1, b17 and a-3/1, contained two ori sequences each; (2) two petite genomes, a-3/1/5 and a-3/1/33, had an ori sequence lacking cluster C, and two petite genomes, a-1/1R/14 and a-1/1R/1/26, had an ori sequence lacking cluster A (ori petites, having a partially deleted ori sequence); (3) petite a-15/4/1 contained two ori sequences in opposite orientations—the only rearranged repeat unit found so far among spontaneous petites (this sort of petite will be indicated as ori'); (4) petite a-15/4/1/10/3, derived by subcloning from the previous one, lacked an ori sequence altogether; another ori petite, a-3/1/B4, was a diploid petite issued from a cross of a-3/1 with wild-type strain B and derived from the 15S-oxi 3 region of the B genome; these ori⁰ petite genomes will be discussed in detail elsewhere.

Figure 2 presents ori sequences 1-5 as determined on the repeat units of 11 different spontaneous petites (see Table 1). The ori 6 sequence and the right end of ori 7 were found in the published sequences of petites DS-400/A12 and DS-14 (refs 16, 17). Homology in the primary structure of different petite genomes carrying ori 1 or 3 was nearly perfect, the very rare differences being indicated by asterisks in Fig. 2. Comparison of different ori sequences indicated perfect homology in clusters A, B and C (some differences in clusters A and B of ori 6 being probably due to sequence uncertainties16 and several differences in region l between clusters B and C.

The stretch shared by all ori sequences is 265 base pairs long, its left border at nucleotide 69, and its right border at nucleotide 334 of Fig. 2. Note, however, that at the left of cluster A ori 6 presents a very large GC cluster, α , absent in at least ori 1-5; (2) ori 4 and 6 contain two additional GC clusters, β and γ , identical in both sequence and location; β is located between clusters B

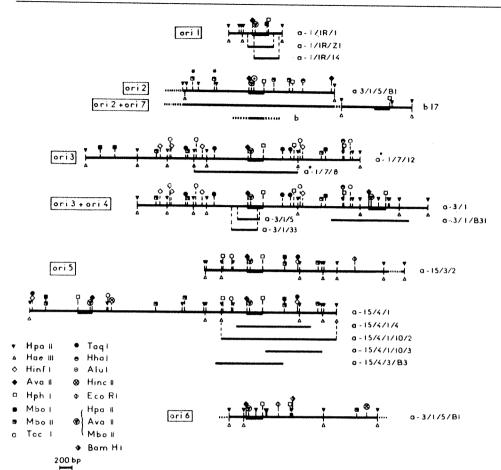

Fig. 1 Restriction enzyme maps of the repeat units of mitochondrial genomes of spontaneous petite mutants. These arose from wild-type strain A, except for a-3/1/5/B1, b17 and b, which derived from a region (oli 1-2) of wild-type strain B in which this genome has the same map as A. Some maps present additions and corrections compared with ref. 5. The map of b17 is a preliminary one; that of b contains an internal deletion in its repeat unit (in preparation). Restriction sites are indicated on some repeat units only and not all AvaII sites are shown. Asterisks indicate restriction sites whose locations need to be confirmed. Ori sequences are underlined: cluster A corresponds to an AvaII site, cluster B to HpaII, AvaII, MboII site clusters, cluster C to a HphI and a MnlI site. All maps are centred on cluster B and oriented with clusters A, B, C, from left to right. Vertical broken lines indicate excision sites where precisely known, bp, Base pairs.

and C, γ at the right of cluster C; at least cluster γ is also shared by ori 7; (3) ori 4-7 are homologous for 30-40 nucleotides at the right of the position of cluster γ ; (4) some sequence homology is present on the left of the ori sequences, particularly in ori 1 and 2; (5) the overall homology between ori 4, 6 and possibly 7 may comprise 370 nucleotides; (6) ori 1 and 2 show homologies for at least 30 base pairs on the right of the ori sequence; and (7) the full sequence of the repeat units of ori petites (ref. 12 and paper in preparation) indicated that these are the result of excisions involving two direct repeats, one of which is within the ori sequence.

Hybridization of labelled petite mitochondrial DNAs containing different ori sequences on restriction fragments from wild-type DNAs has been performed and restriction maps of both sets of DNAs have been compared with maps from other laboratories ¹⁶⁻²⁶. Using these results, it was possible to localize and orient (Fig. 3) ori 1-7 on the mitochondrial genome of wild-type cells and show that the inverted repetition of ori 5 on a-15/4/1 was not present on the wild-type genome. The distribution of the ori sequences is very uneven with five sequences on one-third of the map, the region most often represented among the genomes of spontaneous petites²⁷. Note that ori

Fig. 2 Primary structure of the ori sequences and their flanking regions, as determined by the method of Maxam and Gilbert⁴³ on the repeat units of the mitochondrial genomes from petites a-1/1R/1 (ori 1; position 1 corresponds to position 301 on the repeat unit of the reference sequence of a-1/1R/1)⁷, b (ori 2), a-3/1 (ori 3), a-3/1/B31 (ori 4), a-15/4/1/3/B3 (ori 5), DS-400/A12 (ori 6; from ref. 16) and DS-14 (ori 7; from ref. 17). The sequence on the left of ori 5 is from HS 1948 (ref. 31). Ori sequences were also determined on the repeat units of petites a-1/1R/Z1, a-1/1R/14 (ori 1) a-1/1R/26, a*-1/7/12, a*-1/7/8, a-3/1/5, a-3/1/33 (ori 3). Asterisks indicate the positions of modified nucleotides (indicated as N) or of differences in the same ori sequence as determined on different petites. Regions of ori sequences are indicated by thick lines for GC clusters A, B and C and thin lines for AT regions p, s and l. The positions of clusters β and γ in ori 4, 6 and 7 are given as well as the sequences of these clusters (bottom lines). Restriction sites are indicated by the symbols shown. The sequence of ori 3 corrects some mistakes¹⁴ in the 10 nucleotides at the left of cluster A, and in one nucleotide at the right of cluster B.

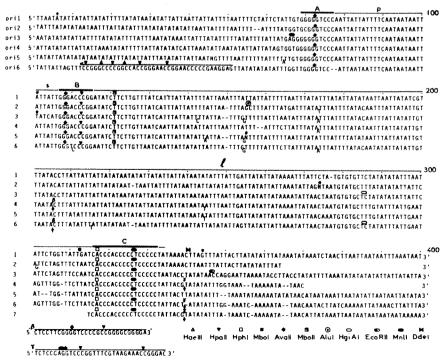

Table 1 The mitochondrial genomes of spontaneous petites: properties of ori sequences and suppressivity

Petite strain	Repeat unit length (base pairs)	Primary structure	Ori sequence	%Suppressivity	Transmission of petite genomes
a-1/1R/1	884	w	ori 1	>95	8:4
a-1/1R/Z1	416	w	ori 1	>95

ь17	~7,800		ori 2+7	80	***************************************

w and o indicate that the primary structure is known for the whole repeat unit or for the ori sequence and the flanking sequences, respectively. All other repeat units were physically mapped (m). The transmission of petite genomes concerns ~200 diploid petites from crosses of sponta neous petites with wild-typestrain B (A in the case of petite b). Mitochondrial DNAs were mapped with restriction enzymes. The ratio presented is that of diploids having the repeat units of the parental petite to diploids having modified repeat units (see text).

* Diploid petites from crosses of spontaneous petites with wild-type cells. The repeat units of a-3/1/B31, a-15/4/1/B3 and a-3/1/5/B1 originated from the genomes of a-3/1, a-15/4/1 and B, respectively. They were used to sequence ori 4, ori 5 and to map ori 6, respectively.

sequences do not have the same orientation (Fig. 3) and that ori 3 and 4, and ori 2 and 7, share a very similar tandem arrangement.

Three independent lines of evidence indicate that the ori sequences are indeed origins of replication. (1) The region between clusters A and B inclusive can be folded in a way (Fig. 4) very similar to that reported for a region of the replication origin of mammalian mitochondrial DNA²⁸⁻³⁰; all base pair changes found in this region in different genomes are localized in the looped-out sequence s. Cluster C is almost identical (Fig. 4) in sequence to a GC cluster, similarly located relative to the A-B region, in mammalian mitochondrial DNAs²⁸⁻³⁰. (2) Ori sequences are present in the repeat units of most spontaneous petites. (3) A clear correlation exists between the properties of the ori sequences and suppressivity, as indicated by the following.

We reported previously that crosses of two spontaneous petites (a-1/1R/1 and b) with wild-type cells produced diploids only harbouring the unaltered mitochondrial genome of the parental petite used in the $\cos^{10-12,14,15}$. Both petites were very highly suppressive (that is, the percentage of petites in the progeny was >95%) and had mitochondrial genomes characterized by very short repeat units (~1% of the wild-type genome). We called these petites, which have also been reported from other laboratories 31,32 , supersuppressive, and suggested that their mitochondrial genomes were only ones found in the progeny because they contained multiple copies of the origin of replication due to tandem amplification of their repeat units and they replicated more efficiently than the wild-type genome, which they could compete out $^{10-12,14,15}$. We have now investigated the general case of petites having any degree of suppressivity. The results are presented in Table 1 and lead to the following conclusions.

(1) Most of the 200 petite diploids had restriction maps identical to those of the parental petites, regardless of the suppressivity of the latter. The few cases where a different situation was found (Table 1) corresponded either to a genome resulting from a new excision process which had occurred in the parental petite genome or, more rarely, in the parental wild-type genome.

(2) Partial or total deletions or rearrangements of ori sequences were always accompanied by drastic changes in suppressivity: the total deletion of ori 5 in a-15/4/1/10/3 resulted in a suppressivity of $\sim 1\%$ as opposed to 90% for

a-15/4/1/4; the deletion of cluster C plus about 100 base pairs on its left in ori 3 led to a suppressivity <5% in a-3/1/5 and a-3/1/33, whereas a*-1/7/8 (although having a much larger repeat unit) had a suppressivity of 85%; the deletion of cluster A in ori 1 caused a decrease in suppressivity, from >95% in a-1/1R/Z1 to 80% in a-1/1R/14 and a-1/1R/1/26; and the presence of a duplicated inverted ori 5 sequence in a-15/4/1 was associated with a suppressivity of $\sim5\%$, whereas a-15/3/2, having a comparable repeat length, but only one ori 5 sequence, had a suppressivity of 50-60%.

(3) The repeat unit length affects replication efficiency as seen by comparing the suppressivities of $a^*-1/7/8$ and $a^*-1/7/12$, two petites carrying the same ori 3 sequence, or of a-15/3/2 and the series a-15/4/1, all containing ori 5. In all cases a shorter repeat length, and thus a higher density of ori sequences, is accompanied by a higher suppressivity. Similar observations have been reported previously⁵.

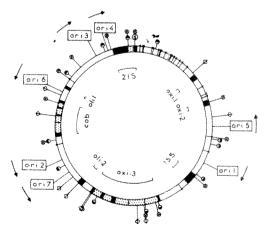

Fig. 3 Localization of ori sequences on the physical map of the mitochondrial genome of wild-type strain A. (This map is almost identical to that of strain KL-14-4 A^{18} .) Positions indicated correspond to cluster B. Restriction sites are indicated by the symbols used in Fig. 1; (§) corresponds to the SaII site, used as the map origin. The orientation of ori sequences is given by arrows pointing in the direction of cluster C. Black and hatched areas correspond to exons and introns, respectively, of mitochondrial genes. Their localization is based on refs 16-26. The localization of tRNA genes is shown by thin radial lines.

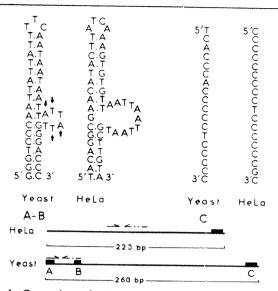

Fig. 4 Comparison of *ori* sequences of mitochondrial genomes from yeast (present work) and HeLa cells²⁸. Homology of potential secondary structure is found for the inverted repeats in the A-B region (arrows indicate the base changes found in this region in different petite genomes). Homology of primary structure is found for cluster C. The bottom compares the two ori sequences; the arrows indicate the inverted repeats of the A-E region, the broken line corresponding to the looped-out sequence. bp, Base pairs.

Two explanations have been put forward to account for suppressivity. The first one proposes a replicative advantage of the mitochondrial genome of suppressive petites over that of wild-type cells³³⁻³⁶. It was directly inspired by the work of Mills et al.³⁷ on the replication of Q β DNA but was not accompanied by any molecular model. The second one proposes a destructive recombination of the petite genome with the wild-type genome³⁸⁻⁴², and predicts that a number of different petite genomes are formed as the consequence of the increased parental genome instability due to the insertion of the petite genome. The present results contradict this latter explanation because most of the diploid petites studied here had genomes identical to those of the parental petites. Indeed, they provide for the first time a precise molecular basis for the former explanation of the replicative competition.

We thank Miss Claire Gaillard, Dr René Goursot and Mr Alain Huyard for help in mapping and sequencing studies, Miss Martine Brient for typing this manuscript and Mr Philippe Breton for the artwork.

The classical cell-surface histocompatibility antigens (H-2 antigens in the mouse), known to have key roles in cell-to-cell recognition1, are encoded by at least three highly polymorphic genes $(H-2D, K \text{ and } L)^2$. Like their human (HLA) counterparts3, H-2 heavy chains span the cell membrane with a short C-terminal cytoplasmic region and an N-terminal extracellular stretch of about 280 amino acids. HLA antigens seem to be organized in three domains containing β -pleated sheets, with disulphide loops within the second and third domains, but the relative scarcity of material has hampered biochemical studies of the H-2 antigens⁴⁻⁶. We now report the sequencing of plasmids carrying H-2 cDNA as a means of inferring the amino acid sequence of the antigens, and especially of their previously poorly described C-terminal half.

The isolation of recombinant plasmids pH-2^d-1 and pH-2^d-3 is described in Fig. 1 legend and elsewhere7. Restriction maps of the cDNA inserts, 1,150 and 980 base pairs (bp) long, respectively, are different, but can be tentatively aligned on PvuII, SstI and PstI sites (Fig. 1). Both inserts contain a noncoding stretch of about 480 bp next to the poly(A) sequence. The 627- and 479-bp long coding sequences and their corresponding amino acid sequences are given in Fig. 2. They show extensive homologies with available sequences of H-2 and HLA molecules (82% with H-2Kb, 73% with HLA B7) (Fig. 3)^{3-6,8-11} allowing unequivocal alignment in the third domain. With reference to HLA3, we assigned nucleotide 133 to the first tryptophan residue in pH-2^d-1 and nucleotide 181 to the first arginine in pH-2^d-3. Both clones should, accordingly, code for the entire third domain, the membrane spanning region and the cytoplasmic segment.

§Present address: Department of Cell Research, The Wallenberg Laboratory, University of Uppsala, Uppsala, Sweden

Fig. 1 Restriction maps of pH-2^d-1 and pH-2^d-3 inserts and strategies to sequence them. The cDNA library from which pH-2^d-1 (ref. 7) was selected had been constructed using mRNA from SL2 lymphoma cells grown as ascites in DBA/2 mice (H-2^d haplotype). The 400 independent bacterial clones of this library were further screened by in situ hybridization²⁹, using a fragment of the insert of the first H-2 clone as a probe. The DNAs of the positive responders were then tested for the specific binding of H-2 mRNA as already described⁷. At least two of them, pH-2^d-2 and pH-2^d-3, were found positive in this test. The cDNA insert of pH-2^d-2 was found identical to part of that of pH-2^d-1, and was not analysed further.

that of pH-2 -1, and was not analysed further. Plasmid DNA was prepared from cleared lysates ³⁰, partially purified by centrifugation in a CsCl/ethidium bromide gradient, and further purified by fractionation through a 5-40% sucrose gradient ³¹. Digestion with restriction endonucleases (Biolabs, Boehringer or BRL) were carried out in standard conditions. Restriction maps were constructed from the size of the DNA fragments, estimated from electropheretic patterns on agarose or acrylamide gels ^{32,33}. As indicated, each cDNA insert is bordered by two reconstituted *PstI* sites ³⁴. Both inserts have the same orientation with respect to pBR322 map. pBR322 sequences are presented here in their usual orientation, so that the parts of the cDNA sequences corresponding to the 3' ends of the messengers are on the left-hand side of the inserts. The coding regions are represented by thick lines. The restriction fragments sequenced are represented by arrows. They were labelled at their 5' (♠) or 3' (♠) ends, and cleaved secondarily to generate subfragments with only one labelled end ³⁵. Sequencing techniques used were those of Maxam and Gilbert ³⁵ (——) or Maat and Smith ³⁶ (———).

THE THE ALB ALB ABP MET ALB ALB CONTROL THE ATT AND ALB CONTROL THE ALB CONTROL THE ATT AND ALB CONTRO

Fig. 2 Coding sequences of pH-2^d-1 and pH-2^d-3. Both sequences have been aligned as described in the text, the 5' terminus is to the left, the 3' terminus to the right. The putative glycosylation (◆) and phosphorylation (♦) sites are labelled. The positions at which a difference is found between the two nucleotide sequences are labelled (●).

A continuous stretch of 26 uncharged amino acids, mostly hydrophobic, extends from amino acids 282 to 307, displaying at the expected position the characteristic features of a membrane-spanning segment. Noticeably, it contains a repetition (Val-Val-Leu-Gly-Ala-Val, followed by Val-Ile-Leu-Gly-Ala-Val) in pH-2^d-1, also seen at the nucleotide level in pH-2^d-3. The amino acid residues differ in 10 out of the 26 positions, suggest-

ing that the major constraint is the sole maintenance of hydrophobicity. No homology with membrane-spanning segments of other membrane proteins was found.

Amino acids 308-338 correspond to intra-cytoplasmic sequences which have been reported to be phosphorylated ¹² and associated with components of the cytoskeleton ¹³. A possible phosphorylation site (Arg-Asn-Thr) ¹⁴ is found at position 313 in

both H-2 clones. At the border with the membrane, a cluster of four basic residues (Lys-Arg-Arg) is found in both clones. As clusters of basic amino acids in similar positions have been found in HLA-A2 and HLA-B7 (ref. 15), membrane-bound IgM¹⁶, human glycophorin¹⁷ and several viral glycoproteins¹⁸, we propose that they might be involved in the positioning of transmembrane proteins.

The amino acid sequence located at the external membrane border shows many variations. The conserved proline residues at positions 276-278 indicate breakage of the α -helical structure, suggesting that this segment can form a flexible link, in agreement with the accessibility of this region to papain⁶.

pH-2^d-1 codes for the third domain and half of the second, whereas pH-2^d-3 codes for the third domain only. Cysteinyl residues at positions 164, 203 and 269 are likely to be those involved in intrachain disulphide bridges, as they are in H-2K^b (refs 4, 5, 19). Possible glycosylation sites (Asn-Tyr-Thr)²⁰ are found at positions 176 and 256 in pH-2^d-1 and pH-2^d-3, respectively. The two amino acid sequences are extremely similar. Divergences are found mainly as clusters (positions 193-198, 225-227, 255-268, 275-303) also seen in comparisons with HLA with additional variations.

The third domain of HLA shares significant homologies with the constant domains of immunoglobulin heavy chains^{21,22} Using the alignment frame designed for HLA²¹, we found that the third domains of the H-2 molecules encoded by the two plasmids display the same type of homology (in preparation). At 20 out of the 23 aligned positions corresponding to hydrophobic amino acids involved in the β -pleated sheet structure in immunoglobulins, hydrophobic residues are also found in H-2 sequences. These results suggest strongly that the third domain of H-2 antigens, like that of HLA, is folded in an immunoglobulin-like three-dimensional structure. When the aforementioned clusters of amino acid differences between pH-2^d-1 and pH-2^d-3 are placed in the three-dimensional immunoglobulin model, they fall in loop areas (in 8 differences out of 10), while β -pleated sheets correspond to highly conserved regions. This suggests that the three-dimensional structure of the third domain imposes constraints on divergences. This could be true for other parts of the molecule as well and be important in the understanding of the basis of alloantigenicity.

Comparisons with available data on H-2D^d, K^d and L^d (Fig. 3) show that pH-2^d-1 differs from H-2L^d at positions 155, 156, 169 and 262. It has a methionine at position 138, whereas the cyanogen bromide cleavage map of H-2K^d indicates that there is no such residue in the molecule²³. At 57 out of 58 assigned positions the pH-2^d-1 amino acid sequence is identical to that of H-2D^d, the only difference being at amino acid 255, denoted as 'tentatively assigned'¹⁰. Therefore, pH-2^d-1 cannot code for H-2L^d or H-2K^d, but could well code for H-2D^d. The pH-2^d-3

Table 1 Analysis of the nucleotide changes between pH-2^d-1 and pH-2^d-3 sequences

	Replacements	Silent substitutions	Total substitutions
Codons 183-284 (third domains)	17/704 = 0.024	5/214 = 0.023	22/918 = 0.024
Codons 285–308 (membrane spanning regions)	7/148.5 = 0.047	2/58.5 = 0.034	9/207 = 0.043
Codons 309-339 (cytoplasmic fragments)	3/221.5 = 0.014	1/66.5 = 0.015	4/288 = 0.014
Codons 183-339	27/1,074 = 0.025	8/339 = 0.024	35/1,413 = 0.025

pH-2^d-1 and pH-2^d-3 were compared over their aligned sequences (Fig. 2). The rate of 'silent substitutions' (see text) was determined by a computation similar to that described by Lomedico *et al.*²⁸: all possible single-step mutations (that is, three possible changes for each base) were totalled over the 157 aligned codons, and classified as replacements if they involved an amino acid change, and as silent substitutions if they did not. The numbers were then averaged for the two genes. The fractions displayed in the table indicate the number of replacements (or silent or total substitutions) actually recorded over the total number of possible replacements (or silent or total substitutions).

sequence differs from H-2D^d at position 262 (ref. 11) and is compatible with the 15 assigned positions reported for H-2L^d in the corresponding area¹¹. It has a possible glycosylation site²⁰ at positions 252-258 as would be expected for H-2K^d (P. Robinson, personal communication). Protein sequence data are thus too limited to allow conclusive assignments, especially as the cloned sequences could also specify Tla, Qa1, Qa2 or other H-2-like antigens²⁴, in line with the finding that the mouse genome contains multiple H-2-related sequences²⁵.

The nucleotide sequences of pH-2^d-1 and pH-2^d-3 diverge in only 47 (9.7%) of the 485 bases aligned for comparison (including 12 aligned with empty positions, Fig. 2). The third domain shows remarkable conservation with only one base change in a stretch of 156 nucleotides (positions 204-255). Surprisingly, silent changes (with no corresponding amino acid change) are unusually rare, compared with replacement changes (Table 1), whereas in other genes the former arise more often than the latter^{26,27}. This raises several hypotheses: a special conservative constraint might exist on the nucleotide sequences themselves, making the silent changes not neutral. Alternatively, the two proteins may have diverged too rapidly to allow the accumulation of neutral mutations in their genes²⁶. Whether this feature is related to a mechanism involved in the generation of the natural polymorphism of these genes or not remains to be investigated.

We thank Miss O. Lebail for technical assistance, Mr B. Caudron for assistance in computer usage and Dr D. Meyer for a critical reading of the manuscript. The work described here was done in accordance with the French and German guidelines for

Neutron diffraction reveals oxygen-histidine hydrogen bond in oxymyoglobin

Simon E. V. Phillips*† & Benno P. Schoenborn†

* MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

† Department of Biology, Brookhaven National Laboratory, Upton, New York 11973, USA

Myoglobin (Mb) reversibly binds molecular oxygen in vertebrate muscle and consists of a polypeptide chain of 153 residues and one haem, which closely resembles one subunit of a haemoglobin (Hb) tetramer. In oxygenated myglobin (oxyMb) the iron atom is coordinated by four porphyrin nitrogen atoms, Nº of the invariant 'proximal' histidine (F8), and molecular oxygen1. The oxygen molecule lies in a tight pocket, bounded by two hydrophobic groups (Phe CD1 Val E11) and the side chain of the 'distal' histidine (E7). This histidine is present in Hb and Mb of many different organisms, with substitution by glutamine or leucine found in only a few cases. The function of the residue is not clear, although it does present steric hindrance to linear ligands such as carbon monoxide and favours 'bent' ones, such as O2. We report here that the imidazole stabilizes bound molecular oxygen with a hydrogen bond, as revealed by neutron diffraction analysis.

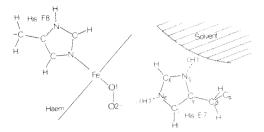

Fig. 1 Arrangement of proximal (F8) and distal (E7) histidines in oxyMb. At pH 8.4, nitrogen-bound hydrogen on E7 imidazole can be bonded to either Nº (the naturally predominant form), with a hydrogen bond to O-2 (dotted line), or to N⁶, where it projects into the solvent surrounding the molecule.

Pauling² first proposed that the imidazole may form a hydrogen bond to the terminal oxygen atom (O-2 in Fig. 1), which carries a formal negative charge in his view of the electronic structure of the FeO2 complex. Evidence suggesting such a bond comes from electron paramagnetic resonance and oxygen affinity data on cobalt-substituted Hb and Mb3-5. The pK of the distal histidine is ~ 5.5 (ref. 4). At physiological pH (and the pD of the crystals used here) the histidine may have hydrogenbonded to either N^{ϵ} or N^{δ} (see Fig. 1), and interaction with O-2 may therefore be by a hydrogen bond, or a simple van der Waals contact. X-ray crystallography of protein crystals cannot distinguish between these alternatives as hydrogen atoms scatter X rays only weakly, and are not normally visible in electron density maps. Neutrons, however, are scattered as strongly by hydrogen and deuterium as C, N, O, S and Fe atoms, and well-ordered H and D atoms may be observed in neutron density maps of proteins^{6,7}.

Crystals of oxyMb were prepared from frozen sperm-whale skeletal muscle¹. Large crystals (8 mm³) were transferred to deuterated mother liquor (pD 8.4) at 20 °C 3 months before data collection, because hydrogen gives strong incoherent scattering of neutrons which increases the background level in diffraction data collection. Replacement of H2O solvent in crystals with D2O, and subsequent replacement of exchangeable H atoms with D in the protein, alleviates this problem and improves the signal-to-noise ratio of the data. It also allows exchangeable H atoms to be identified in the density map, as H scatters out of phase with respect to D.

Neutron diffraction data were collected using the protein crystallography station of the High Flux Beam Reactor at Brookhaven National Laboratory. The diffractometer was equipped with a two-dimensional multiwire proportional counter8 and a cooling device to maintain the crystals at -5 °C and retard oxidation of the haem iron. Two crystals were used for data collection, each being exposed to the neutron beam for 21 days. No radiation damage or oxidation was observed; 88% of available data to 2 Å resolution was collected, together with further data between 2 and 1.5 Å, giving 14,411 independent reflections. The merging R factor between crystals was 14.1% on intensities.

Calculated phases and amplitudes for the neutron data were computed from the coordinates of all C, N, O, S and Fe atoms in the refined X-ray structure1, including 60 ordered H2O molecules. A difference density map (coefficients $|F_0| - |F_c|$: crystallographic R factor 35% for 10,152 reflections with $I > 1.5\sigma(I)$) showed clear peaks for 40% of the missing H and D atoms. Small peaks were visible at both N° and N° of His E7. H and D atoms observed in the map were added to the model, together with unobserved ones whose positions were known from stereochemistry (for example, most C-H groups), but ring nitrogen-bound H or D atoms for histidines were omitted—this reduced R to 33%. A second difference map failed to resolve the ambiguity at His E7, and combined crystallographic and conformational energy refinement was initiated, using methods described for X-ray refinement of oxyMb, but modified for use with neutron data. Seven cycles of coordinate refinement were carried out, with three cycles on individual atomic thermal

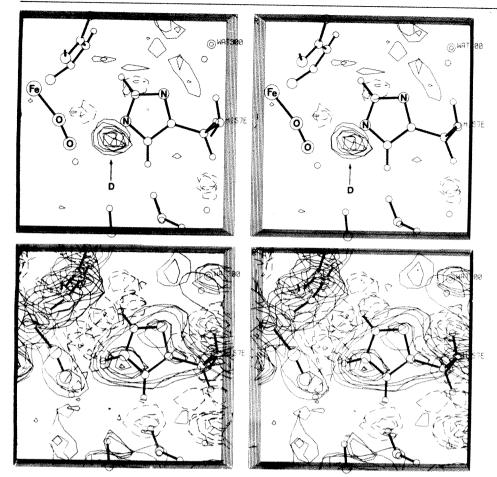

Fig. 2 Stereo view of $|F_0| - |F_c|$ neutron difference density map in a slab 4 Å-thick centred on the plane of E7 imidazole ring. The refined model is superimposed, showing His E7, FeO2 and part of the haem, in a similar orientation to that in Fig. 1. Contours are ± 0.35 , 0.55, 0.75 Fermi per Å, with negative ones shown as broken lines. A strong, positive peak indicates the presence of deuterium bonded to Ne.

Fig. 3 Stereo view of $2|F_0| - |F_c|$ neutron density map in identical orientation to that in Fig. 2. The deuterium has been added to the superimposed model with calculated stereochemistry. The fit to the map is good, although adjustment of the imidazole in later refinement may improve it. Note that whereas D, C, N, O, S and Fe atoms give positive peaks, H scatters out of phase and gives negative peaks. Contours are -1.0, -0.5, 1.0, 2.0, 3.0, 4.0 Fermi per Å³.

parameters, reducing R to 18.8%. A difference map calculated at this stage (Fig. 2) shows a strong peak adjacent to Nº of His E7, indicating the N-bound deuterium. An observed density map (coefficients $2|F_0|-|F_c|$) is shown in Fig. 3, and the high concentration of scattering density at N^s compared with N⁸ confirms the presence of the D atom. As this atom had not been included in the model for refinement or phase calculation, the peaks result from information present in the observed data alone, and are not biased by assumptions about the structure.

The geometry, summarized in Table 1, indicates a medium strength hydrogen bond, although the coordinates may change a little with further refinement when D is included in the model. Such a bond could contribute several kcal per mol to the enthalpy of oxygen binding, and the position of the E7 imidazole might therefore act as a means of control of oxygen affinity in Hb and Mb.

However, direct observation of the hydrogen bond cannot resolve the controversy between proponents of the Fe(III)-superoxide model for oxygen binding^{9,10}, and those favouring a spin-paired model^{2,11-13} with varying degrees of charge transfer between Fe and O2, but it does does suggest that molecular orbital calculations attributing no partial negative charge to O-2 should be regarded with caution, as no hydrogen bond was found between N^e and bound CO, where charge transfer is absent14.

We thank Dr M. F. Perutz for suggesting this experiment and Dr D. F. Koenig for assistance with initial data reduction. This

Table 1 Geometry of histidine-oxygen hydrogen bond

	Distance (Å)*		Angle (degrees)
N°-D	1.04	N^e -DO-2	157
$O-2 \dots D$ $N^{\varepsilon} \dots O-2$	1.98 2.97	O-1-O-2D	96

Deviation of O-2 from plane of E7 imidazole ring is 0.61 Å. Estimated standard deviations for distances, 0.18 Å.

research was carried out in part at Brookhaven National Laboratory under the auspices of the US Department of Energy, with partial support from the NSF.

Modulation of platelet shape and membrane receptor binding by Ca²⁺-calmodulin complex

Kuo-Jang Kao, Joachim R. Sommer & Salvatore V. Pizzo

Departments of Pathology and Biochemistry, Duke University Medical Center, Durham, North Carolina 27710, USA

Interaction between factor VIII/von Willebrand factor, a plasma glycoprotein, and platelets is essential for platelet adhesion and subsequent platelet plug formation at sites of vascular injury during primary phase haemostasis^{1,2}. We now report that binding of ¹²⁵I-labelled factor VIII/von Willebrand factor to its platelet membrane receptors is inhibited by preincubation of washed human platelets with inhibitors of Ca2+calmodulin complex (for example, 50 µM trifluoperazine or

chlorpromazine) at 37 °C for 2 min. Scatchard analysis of the binding data indicates that the total number of accessible binding sites on each pretreated platelet is significantly reduced to ~50% of the original value. There is also negative cooperativity of binding or reduced binding affinity in a major portion of binding sites. Platelet shape changes from diskoid to spherical after treatment. The results suggest that Ca²⁺-calmodulin complex modulates platelet shape and membrane receptor behaviour.

Recent studies suggest that calmodulin, an intracellular calcium receptor, is important in mediating Ca2+-regulated cellular secretion, motility and enzyme activities (see refs 3, 4 for reviews). Trifluoperazine (TFP) and other phenothiazines are known to bind to Ca2+-calmodulin complexes and block their action⁵. It has been demonstrated^{6,7} in human platelets that calmodulin is essential for the activity of platelet myosin light chain kinase, which is responsible for phosphorylation of myosin light chain and subsequent actomyosin contraction. Moreover, platelet aggregation induced by ADP, thrombin, adrenaline, collagen or factor VIII/von Willebrand factor (FVIII/vWF) is inhibited by inhibitors of Ca2+-calmodulin complex, such as TFP⁸⁻¹⁰. The exact mechanism by which inhibition of Ca² calmodulin complex function results in failure of platelet aggregation is unknown. Recently, Gerrard et al.11 reported that platelet membrane glycoprotein III immunologically crossreacts with a-actinin and may anchor actin filaments. Phillips et ² reported a close association between actomyosin filaments and platelet membrane glycoproteins. In view of these findings and regulation of distribution of membrane proteins by cytoskeletal elements in other cellular systems¹³, we have examined the possibility that inhibitors of Ca2+-calmodulin complex inhibit the binding of platelet aggregating agents to their membrane receptors. As we have previously demonstrated that binding of FVIII/vWF to its platelet receptors is responsible for FVIII/vWF-induced platelet aggregation¹⁴, the effects of the Ca²⁺-calmodulin inhibitors, TFP and chlorpromazine (CP)⁵, on platelet shape, and the binding of FVIII/vWF to its platelet membrane receptors were studied.

Human platelets used in these experiments were prepared from citrated venous blood of healthy donors who had received no drugs for at least 2 weeks before the study. Fresh platelets were collected by differential centrifugation¹⁵ and washed first with Tyrode's buffer, pH 7.4, containing HEPES (2 mM), EDTA (5 mM), apyrase (75 µg ml⁻¹) but no Ca²⁺ or Mg²⁺. The platelets were washed again in the same buffer (without apyrase) and resuspended in Tyrode's buffer, pH 7.4, containing 2 mM HEPES. The concentration of washed platelets was determined

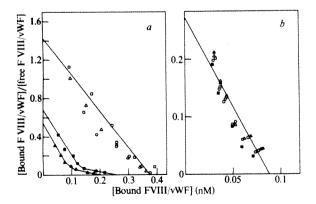

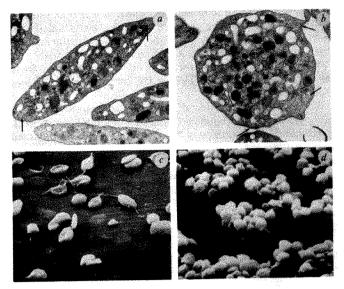

Fig. 1 Scatchard analysis of 125 I-FVIII/vWF binding to platelets pretreated with different phenothiazines. The binding data used for the analysis were obtained by incubating platelets with increasing concentrations of 125 I-FVIII/vWF in the presence of ristocetin (1 mg ml $^{-1}$) as described elsewhere 14 . In a, washed fresh platelets (5×10^6 per incubation) were used. In b, paraformaldehyde-fixed platelets (1.2×10^6 per incubation) were used. \bigcirc , Control; \triangle , TFP pretreated; \bigcirc , CP sulphoxide pretreated. \bigcirc , CP pretreated; \bigcirc , CP sulphoxide pretreated.

Transmission electron micrographs of platelets pretreated with TFP; a shows the control platelets (×24,500). The platelet is diskoid shaped. Electron-dense granules, a granules, and the open canalicular system are visible. Cross-sections of peripheral circular microtubules (arrows) are visible at both ends of the platelet. Similar findings are observed in platelets pretreated with DMSO (0.5%) or TFP sulphoxide (50 µM). b, Platelets pretreated with TFP (50 µM) at 37 °C for 5 min (×24,500); the platelets have become spheroid in shape. Redistribution of microtubules is indicated by arrows. The cross-sections of peripheral microtubules (arrows) suggest that the platelet in b has the same orientation as that in a. The change in shape of platelets after TFP treatment was confirmed by scanning electron microscopy (c, d). c, Control platelets which appear as disks (×33,000). Similar morphology was observed in DMSO (0.5%) or TFP sulphoxide (50 µM)-treated platelets. d, TFP (50 µM)-treated platelets (37 °C, 2.5 min). The platelets appear as spheres (×3,000). Platelets were fixed as described in the text and prepared for scanning electron microscopy as described elsewhere²¹. Platelets were sputter-coated with platinum and examined using an SEM-Phillips 501.

in a haemacytometer by phase-contrast microscopy. The washed platelets were used for all studies of platelet aggregation, FVIII/vWF receptor binding and shape changes. The binding studies were carried out as described in detail elsewhere¹⁴.

To demonstrate that the washed platelets were still responsive to treatment with Ca^{2^+} -calmodulin inhibitors, the effect of TFP or CP on platelet aggregation induced by FVIII/vWF or thrombin was studied by turbidimetry ¹⁴ in a Chronolog model-440 aggregometer at 37 °C. The washed platelets $(5\times10^7\text{ platelets ml}^{-1})$ were aggregated by thrombin (0.5 U ml^{-1}) or by FVIII/vWF $(2\,\mu\text{g ml}^{-1})$ in the presence of ristocetin $(1\,\text{mg ml}^{-1})$. Platelet aggregation was markedly inhibited by either TFP or CP $(50\,\mu\text{M})$ each) but not by the same concentrations of their inactive sulphoxide derivatives (TFP sulphoxide or CP sulphoxide). This result demonstrates not only that platelets are responsive to TFP or CP after our washing procedures, but also confirms the notion that platelet Ca^{2^+} -calmodulin complex plays an essential part in platelet aggregation induced by FVIII/vWF, thrombin or other agents ⁸⁻¹⁰.

The effect of TFP or CP on 125 I-labelled FVIII/vWF binding to platelet receptors was then studied. The specific binding of 125 I-FVIII/vWF to platelets was markedly inhibited when the washed platelets were preincubated with TFP (50 μ M) at 37 °C for 2 min (Table 1). No inhibition of receptor binding was observed when platelets were preincubated with TFP sulphoxide (50 μ M), CP sulphoxide (50 μ M) or dimethyl sulphoxide (DMSO: 0.5%, v/v). Recently, we have demonstrated that platelet membrane FVIII/vWF receptors can be fully preserved after fixation of platelets with 2% paraformaldehyde 14 . To exclude the possible direct interfering effect of TFP or CP on

FVIII/vWF receptor binding, the effect of TFP or CP on 125 I-FVIII/vWF binding to fixed platelets was studied. No inhibitory effect was observed (Table 1). These results demonstrate that neither TFP nor CP directly interferes with 125 I-FVIII/vWF binding to the receptors and that responsive fresh platelets are required for TFP or CP to have any inhibitory effect.

We also studied the effect of different concentrations of TFP on 125I-FVIII/vWF binding (Table 2); an inhibitory effect, apparent after the addition of 25 µM of TFP, reached a plateau after addition of 100 µM of TFP. This dose response is consistent with the observations of White and Raynor¹⁰ who studied the effect of TFP concentrations on thrombin-induced platelet aggregation and serotonin release. The fact that TFP inhibition of platelet-aggregating agents thrombin and FVIII/vWF is concentration dependent suggests that TFP may inhibit platelet function by acting on Ca2+-calmodulin complex.

Kinetic studies were made to determine whether the inhibitory effect of TFP or CP on receptor binding results from reduced receptor binding affinity or a decreased number of accessible binding sites on each platelet. Scatchard analysis of the binding data revealed that the total number of accessible binding sites on each platelet was significantly reduced after platelets were preincubated with TFP or CP (Fig. 1a). Curvilinear Scatchard plots were also obtained. These results indicate either that there is negative cooperativity of binding or that a portion of binding sites shift towards low-affinity binding after pretreatment of platelets with inhibitors of Ca²⁺-calmodulin complex. Again, these effects were not observed in the fixed platelets (Fig. 1b). Our observations suggest that treatment of platelets with Ca2+-calmodulin inhibitors may affect the distribution or the aggregation state of the receptor in the plasma membrane. Thus the accessibility of the receptors for the ligand or the receptor binding behaviour is affected.

We therefore studied the ultrastructural changes of platelets pretreated with TFP or CP using transmission electron microscopy and standard freeze-fracture techniques. Washed platelets were pretreated with different derivatives of the phenothiazines (50 µM) or DMSO (0.5%, v/v) at 37 °C for different time periods. The treated platelets were fixed by adding an equal volume of 1.5% glutaraldehyde in 0.1 M cacodylate buffer pH 7.4, containing 5% sucrose, for 1 h at room temperature. The fixed platelets were sedimented and processed for freeze-fracture using a method described elsewhere 16. Fixed platelets were

Table 1 Effect of trifluoperazine and chlorpromazine on 125I-FVIII/vWF binding to washed fresh platelets and paraformaldehydefixed platelets

	Specific binding (c.p.m.)			
Pretreatment	Washed fresh platelets	Paraformaldehyde- fixed platelets		
Control	37,625 (100.0)	38,624 (100.0)		
DMSO	36,272 (96.4)	38,243 (99.0)		
TFP	17,902 (46.3)	38,204 (98.9)		
TFP sulphoxide	36,068 (95.9)	37,434 (96.9)		
CP	28,594 (75.9)	36,052 (93,3)		
CP sulphoxide	36,220 (96.3)	37,140 (96.2)		

The specific binding of 125 I-FVIII/vWF to 5×106 platelets was determined as described elsewhere 14. The specific radioactivity of the ⁵I-FVIII/vWF protein was 7.3×10⁵ c.p.m. per μg. TFP, CP, TFP sulphoxide and CP sulphoxide were dissolved in DMSO. The platelet suspensions were preincubated with TFP, CP, TFP sulphoxide or CP sulphoxide at 37 °C for 2 min; the final concentrations of all these reagents was 50 μ M. The final concentration of DMSO was 0.5% (v/v). All studies were carried out in duplicate; variation between duplicates was <5%. The experiments were repeated three times, with similar results each time. Only one representative experiment is shown here. TFP sulphoxide and CP sulphoxide are derivatives which inhibit Ca calmodulin complex to an extent which is only 2-3% of that of TFP or CP5. It is unknown whether these derivatives enter platelets. % Binding of control is given in parentheses.

Table 2 Effect of different concentrations of trifluoperazine on 125 I-FVIII/vWF binding to washed fresh platelets

	TFP (uM)					
	0	10	25	50	100	200
Specific binding (c.p.m.)	47,911	48,875	47,111	40,317	20,907	19,400
% of control	100	102.0	98.3	84.1	43.6	40.5

Specific binding was determined as described in Table 1 legend. The specific radioactivity of 125 I-FVIII/vWF was 9.5×10^5 c.p.m. per μg .

also sedimented, fixed by 2% osmium tetroxide, dehydrated and embedded in Epon. Thin sections of sample were cut, stained with uranyl acetate and lead acetate, then examined using a Zeiss EM-10 electron microscope. Results of the study showed that distribution of membrane particles in both the E and P face of the platelet plasma membrane was not affected by pretreatment with TFP (50 µM) or CP (50 µM) at 37 °C for different time periods (2-45 min, data not shown). Nevertheless, thin sections of platelets showed the redistribution of microtubules and that platelets changed from their original diskoid shape into spheres after pretreatment with TFP or CP at 37 °C for 20 min (Fig. 2a, b). This finding was further confirmed by examination of platelets with a scanning electron microscope (Fig. 2c, d). This change in platelet shape was not observed after pretreatment with TFP sulphoxide or CP sulphoxide. Inhibitors of Ca2+calmodulin may effect the change in platelet shape by inhibiting the normal function of actomyosin and microtubules, as it is known that both these cytoskeletal elements are essential for maintaining platelet shape 11,17 and the Ca2+-calmodulin complex regulates microtubule assembly/disassembly and platelet myosin light-chain kinase^{6,7}. In addition, we observed that platelets became spherical after pretreatment with 25 μM TFP at 37 °C for 2 min. The degree of change in shape was not significantly different between platelets treated with 25 μM and 50 µM TFP. However, there was a significant difference in inhibition of 125I-FVIII/vWF binding (Table 2). Thus, it is unlikely that the reduced binding of FVIII/vWF resulted from the change in platelet shape.

Our results are substantiated by recent observations that intra-platelet cyclic AMP inhibits FVIII/vWF binding to platelets 18,19. It is known that cyclic AMP acts as a Ca2+ antagonist by enhancing Ca2+ uptake into the platelet Ca2+ storage sites in the dense tubular system²⁰. The results of this study demonstrate that Ca2+-calmodulin complex may have an important role in regulating platelet membrane receptor behaviour and maintaining the diskoid shape of platelets in the resting state.

Organic solvents modify the calcium control of flagellar movement in sea urchin sperm

Barbara H. Gibbons* & I. R. Gibbons

Pacific Biomedical Research Center, University of Hawaii, Honolulu, Hawaii 96822, USA

The form of flagellar and ciliary beating in various organisms is regulated by the intracellular concentration of free Ca2+ (refs 1-5). In demembranated sea urchin sperm reactivated with 1 mM Mg-ATP2-, Ca2+ regulates the asymmetry of the flagellar waveform⁶⁻⁸. On reactivation at a free Ca²⁺ concentration below 10-8 M. the flagella beat with almost symmetric bending waves, and the sperm swim in nearly straight paths with an average turning rate of ~ 0.04 radians per beat, whereas in the presence of 10^{-3} M free Ca^{2+} , the bending waves are highly asymmetric and the sperm describe circular paths with an average turning rate between 0.2-0.35 radians per beat. Here we show that low concentrations of various organic solvents interact with the mechanism by which Ca²⁺ induces waveform asymmetry. The solvents studied fall into two groups of which the first, consisting of methanol, 2-propanol and ethylene glycol, mimic the effect of Ca2+ and increase the asymmetry, whereas the second group, N.N'-dimethylformamide, formamide and p-dioxane, block the increase in asymmetry induced by Ca2+. However, all solvents in both groups act similarly in decreasing the flagellar beat frequency.

The effects of methanol and dimethylformamide on the asymmetry of reactivated sperm in the presence or absence of added Ca²⁺ are shown in Fig. 1. Methanol increases the asymmetry in both cases. On the other hand, dimethylformamide decreases the asymmetry induced by Ca²⁺ and has almost no effect on the slight asymmetry found in the absence of added Ca²⁺. The decrease in flagellar beat frequency induced by these two solvents is shown in Fig. 2. The preparations of sperm remain almost 100% motile until sufficient solvent has been added to lower the frequency from ~28 Hz to 18 Hz, beyond which the numbers of non-motile sperm increase. Table 1 shows the relative sensitivity of the sperm to the various solvents tested. With most of the solvents, the relative concentrations needed to produce the chosen standard effects on asymmetry and beat frequency were about the same; however, the action of formamide seems to be relatively selective for asymmetry.

The changes in symmetry and beat frequency induced by the solvents seem to be complete within the time of mixing and to remain constant for ~5 min. The effects of methanol and 2propanol seem to be fully reversible if the sperm are diluted 10-fold out of the solvent solution into fresh reactivating solution within ~5 min. The blockage of Ca2+-induced asymmetry by dimethylformamide and dioxane, however, is only partially reversed on dilution of the sperm into fresh reactivating solution containing 1 mM free Ca2+ but no solvent, although the beat frequency immediately returns to its original value. In the average of four preparations, the initial turning rate of 0.32 radians per beat fell to 0.11 radians per beat on addition of 0.9 mol % dimethylformamide and then rose to only 0.17 radians per beat after 50-fold dilution of the solvent. However, the asymmetric beating of such preparations could be fully restored by the addition of 3.2 mol % methanol, or 1.7 mol % methanol and 0.1 mM free Ca²⁺.

Brief digestion with trypsin desensitizes reactivated sperm flagella to Ca²⁺, so that the flagellar bending waves become nearly symmetric even in the presence of millimolar concentrations of free Ca²⁺ (refs 10, 11). This suggests that brief trypsin

digestion destroys one or more structures that mediate the $\mathrm{Ca^{2^+}}$ regulation of asymmetry, while leaving intact the ability of the flagella to propagate symmetric bending waves. We have compared the effect of mild trypsin digestion on the movement of reactivated sperm induced to beat asymmetrically by addition of 3.9 mol % methanol (in the absence of added $\mathrm{Ca^{2^+}}$) with its effect on a control sample containing reactivated sperm induced to beat asymmetrically by the addition of 1 mM free $\mathrm{Ca^{2^+}}$ but no methanol. After addition of 0.2 μ g trypsin per ml of reactivating

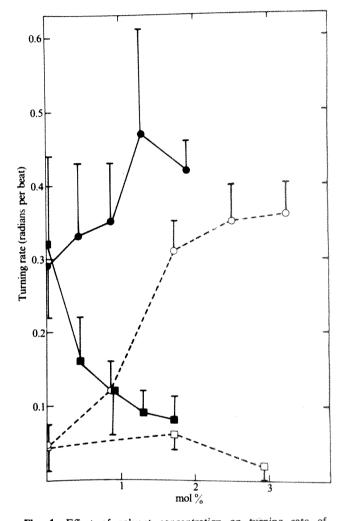

Fig. 1 Effect of solvent concentration on turning rate of demembranated sperm reactivated at 22-23 °C with 1 mM Mg-ATP²⁻ in buffered solution containing either 0.1 mM EGTA (open symbols) or 0.1 mM EGTA and added Ca2 symbols). In these two conditions, the actual concentrations of Ca²⁺ not complexed to EGTA or ATP are estimated to be <10⁻⁸ M and ~1 mM, respectively²³. Procedures for demembranating and reactivating sperm of the sea urchin, Tripneustes gratilla, were as described earlier for 'potentially symmetric sperm' (ref 8). \bullet , Methanol and free Ca²⁺ (~1 mM); \bigcirc , methanol and free $Ca^{2+}(<10^{-8} \text{ M}); \quad \blacksquare, \quad N,N'$ -dimethylformamide and free $Ca^{2+}(<10^{-8} \text{ M}); \quad \square,N,N'$ -dimethylformamide and free $Ca^{2+}(<10^{-8} \text{ M})$ $(<10^{-8} \text{ M}).$ Solvents were Glass Distilled grade from Burdick and Jackson, Inc., Muskegon, Michigan; equivalent results were obtained with highly purified grades from other sources. The solvents were diluted 1:1 with reactivating solution to minimize the heat of solution before addition to the sperm. Concentrations are given as mol % (mol fraction × 100). For comparison with other units, 1.0 mol % equals 2.2% (v/v) or 0.55 M methanol, and 3.3% (v/v) or 0.53 M dimethylformamide. Turning rates were determined from time exposures taken at a magnification of ×160 on Polaroid 3000 Type 107C film by measuring the angle of circular arc travelled by the sperm head during an exposure of known duration. This value combined with the flagellar beat frequency, determined using a stroboscopic flash unit, gave the turning rate in radians per beat. Each point represents the mean obtained from measurements of 10-30 sperm, and the error bars indicate the standard deviation.

^{*} The concentration (mol %) needed to raise turning rate to ~0.34 radians per beat in sperm reactivated with 1 mM ATP at 22-23 °C in a buffer containing 10 mM Tris-HCl, pH 8.1, 0.15 M KCl, 2 mM MgSO₄, 0.1 mM EGTA, 1 mM dithiothreitol and 2% (w/v) polyethylene glycol (molecular weight 20,000).

solution the waveforms became gradually more symmetric at about the same rate in both samples, until after 2-3 min the sperm swam in almost straight lines with apparently normal, symmetrical waveforms. The parallel elimination of both Ca2+induced and methanol-induced asymmetric bending waves by trypsin digestion suggests that these two agents share, at least in part, a common pathway in regulating asymmetry, and that the trypsin-sensitive structure is located in this shared portion.

While the effects of the solvents on asymmetry divide them into two opposing groups, their effect on beat frequency is in the same direction in all cases and may be due to a direct alteration of the kinetic properties of dynein ATPase¹². This second action of the solvents seems to be distinct from their action on asymmetry as it is unaffected by trypsin digestion, and it is also distinct from that of Ca2+, which, at up to 2 mM in the conditions used here, has only a small effect on beat frequency7.

The relative effectiveness of the solvents in altering the asymmetry of flagellar waveforms seems to be unrelated to their dielectric constants, which for solvents of the second group range from ~2 for dioxane to 109 for formamide¹³, while their relative effectiveness on asymmetry varies less than twofold.

Cilia and flagella contain calmodulin-like proteins that presumably act as Ca2+-receptors14-17. Binding of Ca2+ to

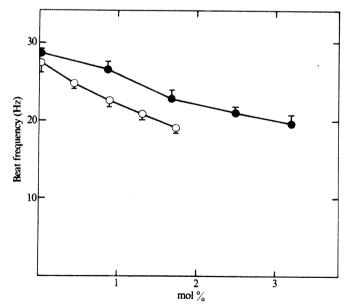

Fig. 2 Flagellar beat frequency of sperm reactivated with 1 mM Mg-ATP²⁻ at 22-23 °C as a function of added solvent: •. Mg-ATP²⁻ at 22-23 °C as a function of added solvent: ●, methanol and free Ca²⁺ (<10⁻⁸ M); ○, dimethylformamide and free Ca²⁺ (~1 mM). Conditions are as described in Fig. 1 legend. Each point represents the mean (±s.d.) obtained from measurements of 8-22 sperm.

bovine brain calmodulin induces the exposure of a hydrophobic surface on the protein which then becomes capable of interaction with various hydrophobic ligands in a manner that may mimic its interaction with the phosphodiesterase molecule in vivo 18. Organic solvents generally induce unfolding of protein structure by promoting the transfer of hydrophobic side chains from internal nonpolar domains of the native structure to the external organic solvent/water solution which provides a less polar environment than water alone 19. Our results could be explained by assuming that methanol and 2-propanol themselves induce the exposure of the hydrophobic surface in a way similar to the action of Ca2+, while dimethylformamide and dioxane (in the presence of elevated Ca²⁺) competitively inhibit the binding of this domain to its subsequent substrate. However, a common feature of the solvents of the second group is the presence of relatively polar, oxygen-containing moieties that could act as hydrogen acceptors and thus interact with proteins by competing for hydrogen bonds, and this provides a possible alternative mechanism for the action of these solvents²⁶. In any case, the fact that the effects described here were induced by concentrations of solvent that are low relative to those frequently used in studies of protein unfolding 21,22, suggests that these solvents have a specific effect on sensitive regulatory protein subunits. Thus, it may be profitable to investigate the effects of these two groups of solvents on other Ca2+-regulated systems as well as on the conformation of the solubilized Ca² receptor proteins.

Co-translational membrane integration of calcium pump protein without signal sequence cleavage

* Laboratory of Cell Biology, The Rockefeller University, New York, New York 10021, USA

† Department of Molecular Biology, Vanderbilt University, Nashville, Tennessee 37235, USA

The calcium pump protein (CPP) or Ca2+-ATPase is the predominant integral membrane protein of the sarcoplasmic reticulum (SR) of skeletal muscle^{1,2}. CPP is a single polypeptide chain of molecular weight (MW) 119,000 (ref. 3) which loops in and out of the membrane at least three times⁴⁻⁸. Recently, a number of integral transmembrane proteins possessing a single hydrophilic domain on each side of the membrane have been observed to use a signal sequence, cleaved^{9,10} or uncleaved¹¹ initiate translocation of their ectoplasmic domain 12. Microsomal membranes when present during translation are capable of correctly integrating these de novo synthesized pro eins into the membrane^{9,11}. We have used this in vitro translocation system to investigate the integration of CPP into the microsomal membrane. We found that CPP is synthesized without a cleaved signal sequence and that it can be integrated into heterologous microsomal membranes only when these are present during translation, but not when they are present after completion of translation.

Translation of mRNA from muscles of 1-day-old rabbits in the wheat-germ cell-free system (in the absence of pancreas microsomal vesicles), followed by immunoprecipitation of the total translation products with sheep anti-rabbit CPP serum yielded a single product (Fig. 1, lane 2) of an apparent molecular weight identical to that of authentic CPP (lane 1).

It has recently been established that CPP translated in the reticulocyte lysate system in the absence of microsomal membranes retains the initiator methionine¹³. However, this experiment did not indicate whether CPP was synthesized with a signal peptide which would be proteolytically removed by the microsomal membranes. To investigate this directly, we performed a partial amino-terminal sequence analysis of CPP synthesized in vitro in the absence of microsomal membranes (Fig. 2) and found substantial agreement with the known sequence of CPP from the SR¹⁴ (Met in position 1; Ala in 3, 4 and 14; Cys in 12). It can therefore be concluded that CPP is synthesized without a cleaved amino-terminal signal sequence. This conclusion is firmly based on previous data which demonstrate that the wheat germ cell-free system per se, that is, not supplemented by microsomal membranes, is free of that signal peptidase activity which cleaves signal sequences addressed to the endoplasmic reticulum. This signal peptidase activity is introduced into the wheat-germ cell-free system only on supplementation of microsomal membranes^{9,15}.

From cell fractionation of muscle and subsequent incubation of cell fractions containing free or membrane-bound polysomes in a protein synthesizing system, it has been established that CPP is synthesized by the membrane-bound polysome fraction ^{16,17}. Based on the criterion of resistance to extraction by low concentrations of detergent ¹⁷, the newly synthesized CPP was integrated into the homologous microsomal membranes.

To investigate whether *de novo* synthesized CPP can be integrated into heterologous (dog pancreas) microsomal membrane vesicles, and if so, whether integration is coupled to translation, we carried out experiments in which microsomal vesicles were present either at the start or after completion of translation.

To assay for integration we had hoped to use protection from limited trypsin digestion as a criterion because tryptic digestion of CPP in SR vesicles is known to yield several discrete fragments that are resistant to further degradation, presumably because of their being embedded in the lipid bilayer4-8 However, we found that the generation of these characteristic tryptic fragments was not the result of integration of CPP into the lipid bilayer. Almost identical fragments were produced when trypsin digestion of authentic CPP was carried out in the absence (Fig. 3, lanes 5-7) or presence (Fig. 3, lanes 2-4) of the nonionic detergent Triton X-100. When the in vitro product was digested with trypsin in a wide variety of conditions, these fragments were never found; regardless of whether the CPP was translated in the presence or absence of microsomal vesicles, only much smaller tryptic fragments were observed (data not shown). This may indicate that the in vitro product never became integrated into the microsomal membranes or that it was

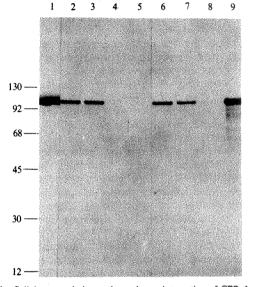

Fig. 1 Cell-free translation and membrane integration of CPP. Lane 1 is from a Coomassie blue-stained gel of authentic CPP2. Lanes 2-9 are from a fluorographed gel of in vitro translated products. Total mRNA was isolated from the limb and back muscles of 1-day-old rabbits¹¹ and translated in the wheat-germ cell-free translation system with ³⁵S-methionine¹¹. Sheep antirabbit CPP serum²⁸ and protein A-Sepharose were used to immunoprecipitate the translated CPP, and the immunoprecipitates were analysed on 7.5-15% polyacrylamide SDS gels and detected by fluorography. Lane 2 is an immunoprecipitate of a 20-µl translation. The specificity of the immunoprecipitation is indicated by the ability of excess (25 µg) authentic CPP to block the immunoprecipitation (lane 4) and the inability of normal sheep serum alone to immunoprecipitate the product (lane 5). Lane 3 is from a 50-µl reaction performed in the presence of microsomal vesicles from dog pancreas²⁹ . Note that the mobility of the in vitro product is not changed. In lane 6, a 100-ul translation performed in the presence of dog pancreas microsomes was incubated for 180 min at 25 °C, instead of the normal 90 min. After translation the pH was adjusted to 11.5 by adding 5 μ l of 1 M NaOH. After 15 min at 0 °C, the 105 μ l was layered over a sucrose gradient in a Beckman airfuge tube which consisted of 80 µl of 0.2 M sucrose and 20 µl of 2 M sucrose. The sucrose solutions contained the same salts as the translation mixture and were also adjusted to pH 11.5 with NaOH. The gradients were centifuged at 160,000 g for 15 min, then 120 µl were removed from the top (supernatant) and the microsomes collected from the 0.2 m/2 M interface and diluted to 120 µl with a solution which contained the same salts as the translation mixture, also adjusted to pH 11.5. Both samples were adjusted to 2% SDS, heated to 100 °C for 5 min, then neutralized and immunoprecipitated. Lane 6 is the immunoprecipitate of the microsomes while lane 7 is that of supernatant. To demonstrate that integration does not occur post-translationally, the same experiment was performed, except that microsomal vesicles were added only after the translation had been incubated for 90 min at 25 °C (at which point no further incorporation of ³⁵S-methionine into protein was detectable) and the incubation continued for a further 90 min at 25 °C. Lane 8 is the immunoprecipitate of the microsomes; lane 9 is that of the supernatant. As a positive control, we demonstrated that an integral membrane protein (the G protein of vesicular stomatitis virus) which is co-translationally but not post-translationally integrated into the dog pancreas microsomes9, will resist extraction in these conditions only when the protein is properly integrated into the heterologous microsomes (unpublished data). The positions of the molecular weight markers (in thousands) are indicated. Froteins used, in order of decreasing size were: Escherichia coli \(\beta\)-galactosidase, phosphorylase B, bovine serum albumin, ovalbumin, carbonic anhydrase and cytochrome c.

integrated but did not assume the native conformation found in the SR. Alternatively, the characteristic tryptic fragments of authentic CPP may be the result of intermolecular association, because CPP exists as an oligomer, both in the membrane 18,15 and in detergent solution20. The in vitro CPP may be present in too low a concentration to form oligomers which might confer partial resistance to tryptic digestion.

As an alternative assay for membrane integration, we determined whether CPP could be extracted by alkaline solution (pH 11.5), as integral membrane proteins are non-extractable²¹⁻²³ By this criterion, about half of the de novo synthesized CPP molecules were integrated into dog pancreas microsomal vesicles, but only when these were present during translation (Fig. 1, lanes 6, 7)—not when they were added after translation (Fig. 1, lanes 8, 9). It remains to be shown, however, whether the observed integration into the dog pancreas microsomal vesicles was normal, that is, whether the folding of the polypeptide backbone in these vesicles is identical to that of its in vivo counterpart in muscle rough endoplasmic reticulum.

The observed coupling between synthesis of CPP and its integration into heterologous microsomal membranes are analogous to those observed previously for translocation of secretory proteins and integration of bitopic integral membrane proteins, suggesting a similar membrane-catalysed mechanism^{12,24}. The recent purification of endoplasmic reticulum-associated proteins²⁵ that catalyse translocation of secretory proteins across the endoplasmic reticulum membrane and the demonstration that these same proteins also catalyse the integration into the endoplasmic reticulum of bitopic integral membrane proteins as well as CPP²⁶ provide strong support for this notion. Furthermore, the efficiency of integration of CPP into the heterologous microsomal vesicles, as assayed by the resistance to alkaline extraction, can be increased to almost 100% by the addition of these purified proteins to the in vitro translocation system²⁶

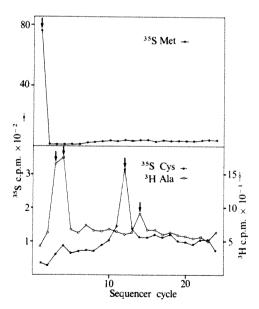

Fig. 2 Partial amino-terminal sequence determination of CPP translated in vitro in the absence of microsomal membranes. Translations (1 ml) were performed using either 35 S-methionine (1,000 Ci mol $^{-1}$) or 3 H-alanine (75 Ci mmol $^{-1}$) and 35 S-cysteine (700 Ci mmol $^{-1}$) (all NEN). Citrate synthase and oxaloacetate were present in the translation mixture to prevent the acetylation of the amino terminus of CPP30. CPP was immunoprecipitated, separated by gel electrophoresis, eluted from the gel and sequenced15

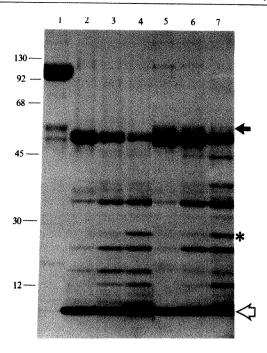

Fig. 3 Tryptic digestion of CPP in the absence or presence of Triton X-100. All samples were analysed by electrophoresis as described in Fig. 1 legend and the gel was stained with Coomassie blue. Each digestion contained, in a volume of 50 µl, 50 µg (protein) of purified SR vesicles, 1 M sucrose, 0.1 M NaCl, 20 mM Tris-HCl, pH 7.5, and the indicated amount of trypsin, pretreated with TPCK. Lanes 2-4 also contained 1% Triton X-100. Trypsin concentrations were: lane 1, 0 μ g ml⁻¹; lanes 2 and 5, 0.6 μ g ml⁻¹; lanes 3 and 6, 6 μ g ml⁻¹; and lanes 4 and 7, 60 μ g ml⁻¹. Digestions were carried out for 45 min at 23 °C and terminated by the addition of 10 µl Trasylol. Solubilization of the SR vesicles by Triton X-100 was ascertained by the inability of the detergent-solubilized vesicles to be pelleted by centrifugation conditions which were calculated to pellet particles with a sedimentation rate >40 S; intact SR vesicles were quantitatively sedimented by these conditions (data not shown). The band indicated by the solid arrow is calsequestrin, a peripheral membrane protein located in the lumen of the SR. It was protected from digestion by the intact vesicles (lanes 5-7) but not when the vesicles were solubilized by detergent (lanes 2-4). The asterisk indicates the position of trypsin. The heavy band indicated by the open arrow is Trasylol. The positions of the molecular weight markers are indicated as in Fig. 1.

MATTERS ARISING

Flexural strength of cements

BIRCHALL ET AL.1 are to be congratulated on the improvements made in the flexural strength of cement, however, we question their scientific explanation which is given in terms of the removal of large size pores ≥100 µm; it is postulated that these pores are simple strength controlling Griffith flaws. We have shown2 that although notched specimens of ordinary cement paste tested in flexure seem to behave according to simple Griffith theory for specimens having a fixed beam depth, nevertheless, when the beam depth is altered different values are obtained for the fracture energy, R. In fact the apparent value of R increases with increasing specimen depth and R is not therefore behaving as a material constant, and a simple application of the Griffith equation is not acceptable. It is apparent from their conclusions that Birchall et al. have carried out measurements on beams of fixed overall depth. Note that in our experiments, specimens of differing size were cut from the same cured samples of cement and therefore the variation in R values could not result from changes in specimen microstructure from one sample to another. By extrapolation we deduced the behaviour of apparently sharp flaws in large cement samples and showed that the material can be regarded as intrinsically weak, for example, for a w/c ratio of 0.3 having an intrinsic strength of ~ 15 MPa, and that sharp flaws have an effective radius of curvature of ~0.5 cm; therefore flaws ≤0.5 cm in size will have a comparatively small effect on strength.

To improve strength it is necessary to increase the intrinsic strength by increasing the total number of effective chemical bonds per unit area of the material for example by reducing the total amount of unfilled space in the material, that is increase density. Birchall et al. quote a value for elastic modulus of 40 GPa for improved (MDF) cement—about twice that of OPC which suggests that its basic structural properties have been changed. We conclude therefore that it is a little misleading to attribute the strength increase solely to the elimination of large flaws and that the high strength has been achieved by a reduction in w/c ratio, good packing, compaction and drying out, all of which are expected to increase strength. The resulting MDF cement, although intrinsically stronger, is sensitive to flaws and will need to be free of macroscopic flaws to achieve the higher strengths; for example a 1-mm flaw will reduce the strength of MDF cement by a factor of 3, whereas a similar size flaw in ordinary Portland cement w/c = 0.3 will only reduce the strength by a factor of 1.6. Therefore, flaws must be eliminated during processing. However, as discussed above, simply eliminating flaws from an ordinary cement paste would not result in strengths as high as those quoted for the MDF cement.

J. E. BAILEY

D. D. HIGGINS

Cement and Concrete Association, Wexham Springs, Slough SL3 6PL, UK

- Birchall, J. D., Howard, A. J. & Kendall, K. Nature 289, 388-89 (1981).
- Higgins, D. D. & Bailey, J. E. J. mater. Sci. 11, 1995–2003 (1976).

BIRCHALL ET AL. have shown that the flexural strength of a Portland cement paste can be increased to ~65 MPa. They termed the modified paste as "macrodefect-free" (MDF) paste and attributed the improvement to the removal of macro-defects. However, this interpretation may be queried.

Birchall et al. have observed that the flexural strength data of both the MDF paste and the ordinary Portland cement paste could be fitted to the Griffith equation.

$\sigma = (ER/\Pi C)^{1/2}$

where "tensile cracking stress (σ) is related to an effective critical crack length (C) which may be a pore; Young's modulus (E) and fracture surface energy (R) being taken as material constants". They found that E and R are 20 GPa and 19 J m⁻² for an ordinary Portland cement paste and 40 GPa and 30 J m⁻² for the MDF paste even though both the pastes have very similar porosities.

It appears that both the material constants E and R are so dependent on the pore size distributions that their product could be altered by a factor of 3. In that case one may wonder how the Griffith equation could be applied to these pastes. This uncertainty has been further emphasised in their Fig. 3 which shows that the MDF paste has higher strengths than the ordinary Portland cement paste even when both pastes have similar sized critical flaws. More probably Birchall et al. have altered the nature of the paste altogether by using rheological aids such as plasticizers and superplasticizers, which are generally organic products of some chain lengths; some even contain organic polymers. The addition of polymers to a cement paste increases its flexural strength as well as its flexural/compressive strength ratio from ~0.1 for a brittle failure to a higher value characteristic of a plastic failure. Note that the MDF paste

has also a flexural/compressive strength ratio of 0.3 (65/200).

It will not be very difficult to ascertain experimentally if the nature of the paste has been modified in which case the observed improvement may have little to do with the removal of macro-defects. Note added in proof: The patent application by Birchall et al.² shows that polymers have been used by them.

BIRCHALL ET AL. REPLY-Bailey, Higgins and Chatterji have raised interesting questions, some perhaps prompted by the lack of detail in our short paper¹. We are aware of the detailed arguments relating to the fracture behaviour of cement paste and of the careful work by Bailey and Higgins on this. Our proposition is that, bearing in mind the heterogeneous and inconstant nature of cement paste, the Griffith criterion is an adequate explanation of the failure behaviour of the material. It has the advantage of predicting what steps should be taken to improve the material—the removal of macroscopic flaws—and our paper shows that this is demonstrably effective.

As Bailey and Higgins correctly point out, fracture tests on ordinary cement paste give a spread of values of R, the fracture energy, a parameter which appears to change significantly with test geometry and crack speed among other variables. We believe that these variations in R make it impossible by conventional experiments to distinguish the Griffith theory from more complex theories of fracture. The experimental scatter is too great. Essentially, what we have done is to extend the study into an unexplored range of flaw size, down to 10 µm, when the overall behaviour is seen to fit the Griffith theory satisfactorily.

It is suggested that the high value of elastic modulus (40 GPa) quoted in our paper for MDF cement indicates a higher number of bonds per unit area or a higher bond strength and a microstructure fundamentally different from that of normal paste. It is indeed implicit in our understanding of the mechanism of hydraand setting², that morphology will vary with the volume of space to be filled and hence with packing, and so on. However, a major point in our paper is that whereas elastic modulus is dominantly related to total porosity volume. flexural strength the

dominantly related to the size and proportion of macroscopic voids and, as illustrated in Fig. 4, is insensitive to total porosity volume. Thus high flexural strength is observed in specimens having a range of values of elastic modulus, 25–40 GPa.

Chatterji suggests that the properties of MDF cement are those of a polymermodified paste. However, the strength values of MDF cement far exceed those claimed for pastes made at modest temperature and pressure in the presence of a water-reducing additive, with polymer addition or by polymer impregnation. Furthermore, the failure mode of MDF cement is brittle with no evidence of plastic deformation. Thus the improved properties of MDF cement are attributable to the altered pore size distribution of the inorganic matrix and are, as we indicate. independent of the chemical nature of the inorganic cement matrix. In this context, other work (in preparation) has shown that MDF cements can indeed be further modified to increase significantly the fracture toughness, with the result that flexural strength is raised still further to levels exceeding 150 MPa. The absence of macroscopic voids is an essential prerequisite for the attainment of such very high strength.

Can passive tactile perception be better than active?

PASSIVE tactile perception has invariably been found to be equal to or inferior to active tactile perception¹⁻³. An exception has recently been reported in an experiment by Magee and Kennedy4 who guided the finger of each blindfolded subject around raised-line drawings of common objects. These (passive) subjects were able to identify more of the drawings than the active subjects whose fingertip movements were unguided. Magee and Kennedy suggest that "the act of planning may draw on the limited resources of the haptic system so that less processing capacity is available to monitor and distinguish relevant from irrelevant kinaesthetic input".

We consider this to be an implausible explanation of active inferiority for the following reasons:

(1) The "act of planning" is more cognitive than sensory. No evidence is provided

to support the idea that, in this experiment, such planning can be expected to interfere with (or draw on limited resources of) the haptic (sensory) system. (2) The resources of the haptic system must be limited at some level of task complexity but the job it was required to do in this experiment should be well within its capacity. When all fingers are simultaneously engaged in palpating an object, the channel is apparently not overloaded. Why should movements on one fingertip tax the system to the degree that planning of such movements proves too much? Moreover, Shiffrin et al.5 present rather convincing evidence for an "unlimited-capacity nonattentional model of tactile perceptual processing". (3) Presumably, "relevant" kinaesthetic input comes from movements made when the fingertip faithfully follows the raised line and "irrelevant" inputs from errors (straying from the line). But surely deviations are important error signals which guide ensuing movements rather than act

either way.

(4) The comparison being made was not simply between active and passive haptic conditions. Rather, because haptic information was so (unusually) impoverished, conscious attention was necessary to build up a "picture"—for both passive and active subjects—but active subjects suffered the disadvantage of also having to plan movements.

as "irrelevancies". Information is gained

In a different experiment, it was shown that when passive and active subjects are yoked in a tactile maze exploration task, the performance of active subjects suffers because they have the responsibility of regulation (planning) of movements⁶. This experiment, and that of Magee and Kennedy, showed that it is possible to demonstrate interference at the cognitive level when information is transmitted by the haptic system—not that passive tactile performance is better than active.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

- Magee, L. E. & Kennedy, J. M. Nature 283, 287 (1980).
 Shiffrin, M. R., Craig, C. J. & Cohen, E. Percept. Psychophys. 13, 328-336 (1973).
- Richardson, B. L., Wuillemin, D. B. & MacKintosh, G. T. Br. J. Psychol. (in the press).

MAGEE AND KENNEDY REPLY—Richardson and Wuillemin argue that our experiments did not establish superior passive tactile perception in the identification of raised-line drawings. They base their claim on studies with tactile finger mazes in which they found passive exploration to be superior to active exploration, and were then able to show that passive superiority was due to a cognitive factor, that is, the act of planning exploratory activity. They argue that passive superiority with raised-line drawings is also due to this cognitive factor.

Modern theorists recognize that planning and anticipation are crucial to perception, and we too recognize this as a critical component of haptic perception. However, the crucial problem for present purposes is that Richardson and Wuillemin's conclusion is based on superficial similarity between two types of tasks rather than on fundamental principles of haptic perception.

Clearly, Richardson and Wuillemin's finger-maze learning could be solved as a verbal sequence of eight discrete left-right turns¹, a number within the bounds of short-term memory. In contrast, the identification of raised-line drawings involves complex shape information that is not discrete. Our subjects had to deal with a line continuously varying in location, direction and extent, that is, the task required the subject to integrate across time subtle spatial information that was difficult to encode verbally. Integrating all this information was not easy, as shown by the generally low levels of performance on this task. These low levels of performance indicate (contrary to Richardson and Wuillemin's assertion, made without supporting evidence) that our singlefinger task was not facile and was not well within haptic capacities. Richardson and Wuillemin's task has little to do with perception, while identifying shape and form is the sine qua non for haptic perception.

Our task was one of haptic perception in which we have shown passive superiority.

HUMAN IMMUNOLOGY

Official Journal of the **American Association for** Clinical Histocompatibility Testing

Editor-in-Chief D. Bernard Amos Department of Immunology and Microbiology **Duke University Medical Center** Durham, North Carolina

Managing Editor Glenn E. Rodey Barnes Hospital Washington University School of Medicine St. Louis, Missouri

Human Immunology is international in character, encompassing basic and clinical, human and nonhuman studies that promote understanding of the HLA complex and genetic regulation of the human immune response.

This exciting and timely journal is a compendium of information for clinicians and researchers concerned with the latest developments in immune responsiveness.

The Editorial Board consists of thirty-six internationally distinguished scientists and clinicians.

Aims and Scope

Human Immunology is concerned with the regulation and control of immune responsiveness and how failures of these functions result in disease. Principal emphasis is on the role of components of the major histocompatibility complex

(MHC) in disease. Full-length articles, critical reviews and commentaries, brief communications, and technical procedures on basic mechanisms, applications to disease processes, and technical developments will be considered for publication.

BOOK REVIEWS

The genius phenomenon

Donald Michie

John von Neumann and Norbert Wiener: From Mathematics to the Technologies of Life and Death. By Steve J. Heims. Pp.547. ISBN 0-262-08105-9. (MIT Press: 1980.) \$19.95, £14

THE appearance of S. J. Heims's study of John von Neumann and Norbert Wiener is opportune. Technologies of computing, communication and control sprang from where the two men sowed, and are now taking us beyond range of our charts. Will the cybernetic age resemble other ages? Will scientists still be "on tap but not on top"? Or did the post-war influence exerted by physicists and mathematicians in American military circles presage new responsibilities for a stratum of society commonly regarded as temperamentally ill-equipped to bear them?

If so, it seems that we may have to accustom ourselves to receiving guidance from our emotional juniors on matters of life and death. The saving that "genius is to madness near allied" was always of course misleading. But if one were to decide to call infants mad for their helpless and grasping self-absorption, and adolescents mad because of their lonely assertiveness and intensity, then we could read meaning into the saving after all. The association between one or another form of emotional underdevelopment and extreme manifestations of creative excellence has often been remarked. It finds fascinating exemplification in Dr Heims's book about information science's two great founders.

Norbert Wiener no doubt started life as an infant; but if by some mischance he did not, then he later repaired the omission. Thus, Bertrand Russell, writing in 1913:

At the end of September an infant prodigy named Wiener, Ph.D. (Harvard), aged 18, turned up with his father who teaches Slavonic languages there, having first come to America to found a vegetarian communist colony, and having abandoned that intention for farming, and farming for the teaching of various subjects, [say] mathematics, Roman Law, and mineralogy, in various universities. The youth has been flattered, and thinks himself God Almighty — there is a perpetual conflict between him and me as to which is to do the

Socially unsure to the end of his life, Wiener's child-like attributes of generosity and utopian optimism struck all who knew him. There were also irritants — absentmindedness, simulation of sleep during the lectures or conversations of others, and the constant and overwhelming hunger for praise. The latter would impenitently break surface even when to all appearances it had

been totally transcended. A friend recalled a meal towards the end of Wiener's life:

... Wiener stopped and turned the conversation to Yilmaz (a physicist). Now people say that Wiener wasn't good at listening to people. Wiener was perfectly quiet as Yilmaz expounded his color theory ... then we went on to invariance, and science and epistemology; the conversation then took on a very general tone. I remember it was a beautiful, sunny day; it was a very heady experience; we were really getting along perfectly. Then at the end Wiener said to me: 'Was I a good listener?'.

I met Norbert Wiener at Oxford around 1950. N. A. Mitchison and I, with other graduate students, took him to Mitchison's rooms in Magdalen after he had talked to an undergraduate society. We settled him in an arm-chair, where he seemed to fall at once into a deep sleep. We began to discuss genetics among ourselves. This was a year or two before Crick and Watson had identified the genetic material in people's minds with DNA and had proposed the existence of a coding problem. Wiener's eves opened briefly: "How many bits of information, I wonder, are coded in the human chromosomes? Could one, do you think, get an upper bound by chemical arguments?". He closed his eyes. We exchanged glances, and having missed the whole of a very extraordinary point resumed our aimless talk.

Wiener's youthful attention was drawn by Russell to Einstein's 1905 paper on Brownian motion. Marc Kac wrote after Wiener's death:

In retrospect one can have nothing but admiration for the vision which Wiener had shown when, almost half a century ago, he had chosen Brownian motion as a subject of study from the point of view of integration. To have foreseen at that time that an impressive edifice could be erected in such an esoteric corner of mathematics was a feat of intuition not easily equalled now or ever. . . It gave us not only a new way of looking at problems but actually a new way of thinking about them.

The man who in the late 1940s founded cybernetics, supervised in the early 1960s a PhD student in a further development of this early work on stochastic processes. The student, Michael Arbib, has gone on to establish at the University of Massachusetts a Centre for Systems Neurosciences coherent embodiment of Wiener's dream of a mathematical school for the analysis of biological organization and its control. Every great scholar hopes to leave more than his writing. Wiener, in surveying today's work on formal models of brain function, would I think be satisfied both with the project itself and with its humanistic goals.

Norbert Wiener (top) and John von Neumann. Both "loved to dazzle and [were] preternaturally equipped to do so".

From first to last Wiener followed Descartes: "I would not engage in projects which can be useful to some only by being harmful to others". His penalty was to be the eternal mavenick — "calf or other animal not marked with an owner's brand".

Von Neumann's consuming drives presented a contrast to all this. Like Wiener, he loved to dazzle and was preternaturally equipped to do so: Leo Wigner referred to his brain as "a true miracle". But he made sure to dazzle as an insider. In the higher counsels of the Pentagon he showed a demonstrative hawkishness beyond that of the less rootless, less

intellectual, professional hawks of the military. In 1950 he was remarking: "If you say why not bomb them tomorrow, I will say why not today? If you say today at 5 o'clock, I say why not one o'clock?".

In connection with von Neumann's advocacy of preventive nuclear war, Steve Heims writes of his response when asked by Ulam to explain the "Hungarian phenomenon":

... he would say that it was a coincidence of some cultural factors which he could not make precise: an external pressure on the whole society of this part of Central Europe, a subconscious feeling of extreme insecurity in individuals, and the necessity of producing the unusual or facing extinction.

Edward Teller remarked of his youth that Hungary was foundering and if he wanted to survive he would "have to be better, much better than anyone else", echoed by another scientifically spectacular émigré, Davis Gabor: "Innovate or die!".

The Hungarian phenomenon may or may not be overemphasized in this book. But as concerns John von Neumann's desire to be not just on tap, but on top, Heims is replete with vivid documentation. A picture takes form of breath-taking intellectual exuberance and power lodged in a coldly ambitious yet sanguine personality, both complex and strangely undeveloped. When the author writes, in connection with the creation of nuclear weapons, of von Neumann's "compelling desire to serve and be part of the élite establishment, and to assume a modern American role reminiscent of the court astrologer or court engineer of a feudal military empire", we recognize it for the truth. We also recognize that von Neumann himself in all likelihood would jauntily have accepted the label for ornament. Among Johnny's attributed sayings was: "Only a man from Budapest can enter a revolving door behind you and emerge ahead of you".

Wiener's tangible legacy groups itself around the foci of neurobiology and cognitive science. Von Neumann's is to be found in the technology of brute-force computing, rather than in today's developments in artificial intelligence. Although aware of A. M. Turing's contributions to logic, to computer design and to the mechanization of human thought processes, von Neumann showed little sign of having received an influence. The notion of resource-limited computation, key to the brain's cognitive processes and their machine simulation, would surely have been alien to one whose reluctance to admit limits to his own calculational powers became a byword. A similar assumption of omniscient rationality lies at the root of the game-theoretic model of economic behaviour which was erected by him and Morgenstern, now displaced by H. A. Simon's notion of practically feasible, as opposed to ideal, calculations of selfinterest.

In one respect, Heims's book follows a popular error. Von Neumann is credited with sole intellectual rather than political authorship of the EDVAC design. This doubtless arises from the circumstance that the report of the EDVAC committee, which included Eckert and Mauchly, bore the sole signature of its chairman.

In general, however, Steven Heims's scholarship is both voluminous and detailed, and his personal biases, which are those of a liberal humanist, are not too obtrusive. The author succeeds least in his attempted tour of the pure and applied mathematics which these men built, in von Neumann's case outstanding in this

century. For this we must wait for another book. But the living substance of two great minds and of the convulsive epoch through which they lived is here recreated in 414 pages of narrative and 115 of notes. The book informs, stimulates and entertains. In its cumulative effect it also profoundly disturbs. It is right that we scientists should be induced to contemplate our professional responsibility for the repercussions of our trade. The labours of Dr Heims have fashioned a powerful instrument to this end.

Donald Michie is Professor of Machine Intelligence in the University of Edinburgh,

New dimension for archaeology in tool use

Ruth Tringham

Experimental Determination of Stone Tool Uses: A Microwear Analysis. By L. Keeley. Pp.320. ISBN hbk 0-226-42888-5; ISBN pbk 0-226-42889-3. (University of Chicago Press: 1980.) Hbk \$15, £10.50; pbk \$7, £4.90.

AMONG the spate of literature accompanying the rise of interest in prehistoric artifact use, two books stand out: Lithic Use-Wear Analysis, edited by Brian Hayden (Academic, 1979), and this volume by Lawrence Keeley.

Experimentation forms the most important aspect of Keeley's research, and it comprises the third and fourth — by far the most important — chapters of his book. The two preceding chapters discuss recent research on microwear and the method of the microscopic examination of the edges of stone tools.

For Keeley, experimentation is the "fabrication of replicas of archaeological implements and their use on various materials under controlled conditions" (p.3), the ultimate purpose of which is "the interpretation of particular archaeological pieces usually from archaeological occurrences limited in time and space" (p.5). The value of such replications is that they help to bring alive long-vanished patterns of behaviour, and suggest directions for more systematic research. The series of replications reported by Keeley in detail describe the formation of polishes on the surfaces and edges of flint flakes as a result of contact with different materials in different tasks. These polishes are then identified on archaeological specimens and inferences made about the material and the task of the prehistoric tool.

Keeley's replications, however, have limited implications for general issues of the evolution of human behaviour. In fact they are not really "experiments" in the definition of the term used in experimental sciences, in that they are not designed to test empirical hypotheses by the systematic and artificial manipulation of variables.

They do not explain the nature of the properties of the raw materials being tested. As Keeley is the first to point out (p.167), his replications do little to explain the variation in the character of the polishes formed on the flint. On the other hand, he criticizes as artificial such experiments as my own which do not replicate purposeful tasks but, under laboratory conditions, mechanically bring tool edge and worked material into contact in a repeated and standardized action. And yet to criticize such experiments as "artificial" misses the whole point of experimentation.

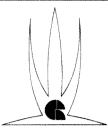

In spite of this inherent theoretical weakness in the book, there is no doubt that Keeley has made a methodological breakthrough in microwear studies by focusing on an essential aspect of the reconstruction of the utilization of stone tools — the correlation between the variability of polishing of flakes and that of the worked material.

The second major section (Chapters 5-7) reports the observations which Keelev made on prehistoric tools and the application of this microwear information to the interpretation of variability in three Lower Palaeolithic assemblages from southern England (Clacton, Swanscombe and Hoxne.) Here, as stated earlier in the book, Keeley's main aim is to reconstruct task-specific behaviour in his sites and assemblages. Yet his conclusions from microwear observations of the three assemblages do not directly address this problem. The observations provide information on the utilization of rock as a raw material resource rather than on the activities which the tools performed. On the basis of microwear information, Keeley concludes that the utilization of flint as a source of tool raw material was opportunistic and relatively unplanned in the Clactonian and Acheulian industries represented by his three sites. Selection of flakes for specific tasks, if such selection existed, was on the basis of the shape and

angle of the edge, not on the shape and size of the flake itself. There is a most interesting discussion on the relationship between the role of hand-axes and flake tools in the stone tool assemblages, which of course is pertinent to our understanding of the changing use of stone as a raw material between the Lower and Middle Palaeolithic industries, hand-axes being much rarer in the latter. It is unfortunate that so far very little microwear information has been collected on hand-axes. As Keeley points out, "there is much potential for future research".

The implication of Keeley's conclusions in this section is that microwear data can provide unique information on the use of stone by allowing us to relate empirically the form of artifacts to their utilized parts. Furthermore, such data can provide the sole source of information on an aspect of the evolution of human behaviour which has received little discussion by archaeologists — the consumption of resources: their uses, maintenance and discard. But it seems that Keeley does not recognize this broader significance of his work.

Similarly, the two concluding chapters are somewhat disappointing. They discuss, respectively, areas for future research and the conclusions of the study so far, and both are characterized by a surprising modesty and lack of ambition. The conclusions of the microwear analysis of the prehistoric assemblages which Keeley (p.176) feels are the most important are that it has "... uncovered many fascinating details about the technology of the Lower Palaeolithic, not the least of which are the existence of plant 'gathering' knives and information about the methods of hide preparation employed"; furthermore, it has "uncovered some interesting relationships between the morphology and function of implements in the assemblages . . . ", and it has provided a "little tantalizing information pertinent to questions concerning the purposes of hand-axes in the Middle Acheulian . . . ". But is microwear analysis — all those hours and energy — destined to provide only the "fascinating", the "tantalizing" and the "interesting"? Likewise, the suggestions for future research tend to concentrate on particular details and problems.

In this book there is an enormous amount of valuable experimental and analytical information, which should have an impact on a wide public. Keeley warns about many of the traps of microwear analysis, including over-confidence and over-optimism. He fails, though, to mention the most dangerous one of all: that one can fall in love with one's flake edges, especially when they are viewed under the microscope, and forget why it is that we originally decided to spend so much time with them.

Ruth Tringham is Associate Professor of Anthropology at the University of California at Berkeley.

Natural history from Henry VII to Victoria

G. D. R. Bridson

British Natural History Books, 1495-1900: A Handlist. By R.B. Freeman. Pp.437. ISBN 0-7129-0971-0/0-208-01790-0. (Dawson, Folkestone, Kent/Archon, Hamden, Connecticut: 1980.) £20, \$39.50.

Modest proportions and unpretentious presentation combine to disguise this book's place as a milestone in the progress of British natural history bibliography. We have never had an equivalent of, for instance, Meisel's magnificent bibliography of American natural history down to 1865, though such works as Simpson and Henrey for botany, and Irwin and Lisney for ornithology and entomology, have made significant contributions. Otherwise one could turn to the German compilations of Engelmann, Carus and Taschenberg for a bibliography of general natural history and zoology down to 1880, amongst which is buried British material.

The compilation of a checklist of all British natural history books is a task for the experienced bibliographer and we are fortunate that one so well qualified as Dr Freeman should attempt the task. The result is a work that does great credit to him and outstanding service to the user. It is only a handlist but within that format lies much concealed scholarship and great attention to accuracy. This is enhanced by providing the full forenames of every author possible, by searching out and recording multiple editions, by providing a chronology of pre-1801 titles and by indicating in the index "those works which, in the opinion of the author, are the most important contributions to the subject of the entry". The 35-page subject index extends the value of the book beyond that of a handlist, though that still remains its basic function and as such it is remarkably comprehensive. One can find omissions among its 4,206 entries by crosschecking with works such as Jackson's guide to botanical literature or Taschenberg's general natural history listings. But, I must stress, so much is included that only specialists in book rarities will find fault.

What is more controversial is the exclusion of papers in periodicals and, unfortunately, any bibliographical

In celebration of the centenary of the British Museum (Natural History), the Museum and Cambridge University Press have published *Chance, Change and Challenge*, a two-volume illustrated compilation which will be of particular interest to sixth-formers and undergraduates. Volume 1, *The Evolving Earth*, deals with the origin and development of the Earth, and Vol. 2, *The Evolving Biosphere*, examines the evolution of life. Prices are: Vol.1 hbk £30, pbk £10.50; Vol.2 hbk £32.50, pbk £11.50.

reference to the periodicals themselves. This a handlist of books, but just when a preprint, offprint, reprint or plain tear-out becomes a separate book will give rise to much argument in many individual cases. So many papers from periodicals were reprinted, often with new pagination, in the nineteenth century that the full record of this transition literature will take many years to document with accuracy. The exclusion of bibliographical mention of periodicals is, in my view, the book's most serious omission and one that would not have required so much effort to rectify.

Librarians, bibliographers, historians, book-collectors, booksellers and naturalists will all want this work on their shelves for frequent reference, and several of those will wish to interleave and annotate their copies. They will find few typographical errors to correct, an odd binary entry to delete perhaps (for example Nos. 439 and 1,181), and a few cross-references to add here and there. At £20 the book is rather costly for such commonplace presentation but in terms of intrinsic value and likely duration of utility that cost will be amply rewarded.

Howard Hinton's eggs — a monumental bequest for entomology

Charles Neville

Biology of Insect Eggs. By H. E. Hinton. Pp.1,125. Three volumes. ISBN 0-08-021539-4. (Pergamon: 1981.) \$400, £167.

THIS posthumous work is monumental in both senses of the word. Professor Hinton tried courageously to finish it during his terminal illness, but the final stages of publication, including compilation and checking of the extensive references and index, had to be completed by his research assistant, Mrs Joyce Ablett, and by Dr Colin Mapes. Information on insect eggs was previously scattered throughout the literature. It now becomes available in one source, which is certain to become the standard work on the subject. But these three volumes constitute no mere review: they also contain an enormous amount of original information, based upon a lifetime of work divided between field and laboratory.

The egg stage of insects is no less important than those which follow. Yet most entomologists would be content if they could recognize even the adult stage of those species of flies found on cow pats. Howard Hinton could, however, with the aid of a hand lens, identify their eggs down to species in situ. As might be expected from one of the world's most knowledgeable entomologists, the text is packed with interesting examples of evolutionary adaptations.

Some of the most fascinating arise from the fact that, being small, insect eggs have a relatively large surface area. Whereas this is an advantage for oxygen uptake, it means that terrestrial eggs are prone to desiccation; conversely, eggs in aquatic surroundings are threatened by drowning. Professor Hinton shows how these factors explain the greater complexity of insect eggshells compared with those of larger animals, and relations between respiratory structure and function receive extensive coverage in the first volume. The inner layer of insect eggshells is filled with air, and it communicates with the outer surface through channels (aeropyles), some of which open on elevated turrets, or even horns. In some eggs, which might otherwise drown, trapped air bubbles function as gills which both provide oxygen themselves and give access to a further supply from the surrounding water. Such bubbles eventually shrink, however, and need replenishment. This is fine for motile stages but not for eggs, which cannot move. To solve this problem, some eggs which are laid in dung begin respiration by a shrinking bubble, and then change over to a constant-volume bubble trapped between hydrofuge hairs (a respiratory plastron). Hinton has shown how there are even more examples of plastrons in terrestrial eggs than amongst aquatic larvae. Plastrons are particularly

appropriate for eggs which are subjected to alternate drying and flooding, and have independently evolved in unrelated species many times. A further chapter describes how some eggs can absorb water via special organs (hydropyles).

Subsequent chapters in the first volume cover the interrelations between adults and their eggs (fecundity, oviposition and parental care). There are also chapters on the adult glands which secrete protective egg cases; on the proteins which form them; on eggshell proteins and their chemical cross-linking; and on how eggs interact with their enemies, often fooling them with deceptive colours or shapes.

The second volume describes the egg structure and adaptations of insects, order by order. Numerous keys to identification will prove invaluable to future workers, though, sadly, there was not time for a chapter on fleas. These two volumes are profusely illustrated: I counted 911 photographs, mostly original scanning electron micrographs, a technique which Howard Hinton used right from its introduction. In addition there are 32 tables and nearly 300 clear text diagrams, most of which are original.

The final volume provides the overwhelming bibliography (over 5,000 references) and separate indexes to species, authors and subjects. The work ends with a list of Professor Hinton's publications: these three volumes now complete it. His contributions to entomology thus end on a resounding note.

Charles Neville is Reader in Zoology at the University of Bristol.

Children who are left to themselves

P. E. Bryant

Developmental Psychology and Society. Edited by John Sants. Pp.389. ISBN 0-333-21340-8/0-312-19751-9. (Macmillan Press, London/St Martin's Press, New York: 1980.) £20, \$35.

D. W. WINNICOTT, a well-known child psychiatrist, is quoted as having remarked in a heated discussion that there is no such thing as a baby. He meant that it is absurd to treat babies in isolation. They are in constant contact with parents and others, and most of the significant things that they do are social in some way or other. This is a point which most child psychologists accept nowadays, but they still find it hard to incorporate into their work.

The clearest example is the question of the importance of language in intellectual development. It seems obvious that people talk to children and tell them things, and that this contributes significantly to the child's growing understanding of his world. Yet the effects of this sort of communication have been virtually ignored by child psychologists. Some, like Piaget, go to great lengths to show that language is of small importance to a child's development; others think that it might have some effect but in the form of "inner speech" - the child talking to himself. Nobody seems to realize that grown-ups actually talk to children. As usual, the social element is left out.

The great merit of the book which John Sants has edited is that it attempts to fill this gap. Nevertheless, the clearest point to emerge is how indirect our knowledge is of the effects of different kinds of social contact. Even the best chapters show this. Those, for example, by Roger Goodwin on

language and by Neil Warren on crosscultural psychology are particularly impressive. Both are comprehensive and entertaining. But the chapter on language has virtually nothing on people talking to each other — rather odd in a book with society in its title — and the cross-cultural chapter is more concerned with connections between "primitive" and child-like mentalities than with the transmission of culture from one person and generation to another. The topics seem to be social, but the meat of social behaviour — social interactions — is left out.

A more glaring example of discrepancy between appearance (the chapter heading) and reality (what lies beneath) occurs in Wallace's chapter on educational competence. Nothing is said in it about teaching the child, who is left to get on with his own development without any help from anyone else. This abandonment reflects a Piagetian bias, which also dominates a chapter by Furth on Piagetian perspectives. Nothing social there, and very little in a chapter by Archer and Lloyd on sex differences. The closest one gets to social interactions is in an interesting though speculative chapter by Trevarthen on very early physiological and social development, and by Isbell and McKee on social cognition.

None of the authors should be blamed too harshly for neglecting social interactions in a book on children in society. It is the fault of developmental psychology, which still has to get to grips with Winnicott's insight.

P. E. Bryant is Watts Professor of Psychology at the University of Oxford.

Electron Microscopy of Proteins

edited by J.R. Harris

Volume 1: September/October 1981, c.350pp., 0.12.327601.2.

Volume 2: December 1981, c.350 pp., 0.12.327602.0.

In the preface, Professor R.W. Horne, Department of Ultrastructural Studies, John Innes Institute, Norwich, England writes: "These volumes reveal the remarkable progress made in the field of morphology closely linked to biochemistry and biophysics. The contributors are distinguished experts within their own areas of research, which will provide the reader with an up-to-date account of the exciting and new developments in determining the structure of a wide range of proteins with the aid of the electron microscope.

Heterogeneity of Mononuclear Phagocytes

Proceedings of an International Workshop held in Vienna, July 15-19, 1980.

edited by Othmar Förster and Maurice Landy

July/August 1981, xxxviii + 538 pp., £16.40 (UK only)/\$39.50, 0.12.262360.6

The concept of the mononuclear phagocyte system was developed in the early 1970s, based on the observation that macrophages and other phagocytic mononuclear cells are derived from a common ancestor in the bone marrow. Various functions have been attributed to these cells. These include effector functions such a phagocytosis and the killing of micro-organisms; cytostatic and cytotoxic effects against tumour cells and parasites; the functions of an accessory cell against tumour cells and parasites; the functions of an accessory cell in the specific immune response; the secretion of biologically active molecules like enzymes, complement components, interferon and prostaglandins. This volume contains much recent research concerned with the correlation of these functions with the various subtypes of these cells: whether variation represents different stages of development or, alternatively, separate lines of differentiation or other functional differences associated with cell

Mechanisms of Sex Differentiation in Animals and Man

edited by C.R. Austin and R.G. Edwards

July/August 1981, xvi + 604pp., £37.00 (UK only)/\$89.00, 0.12.068540.X.

With the collaboration of Dr Ursula Mittwoch, the editors have written an introduction to the subject including one or two major topics that are not covered in the main body of the book. The subsequent papers, each written by recognized authorities in their particular fields, provide a readable, informative and contemporary description of current ideas and research in the study of sex determination. These include genetic and environmental mechanisms of sex determination, sexual endocrinology of fetal and perinatal life, and the nature and origin of sexual anomalies such as hermaphrodites, freemartins, mosaics and chimaeras, in both animals and man.

Eighth Sigrid Jusélius Foundation Symposium, Helsinki, Finland. June 1980.

Expression of Eukaryotic Viral and Cellular Genes

edited by Ralf F. Pettersson, Leevi Kääriäinen, Hans Söderlund and Nils Oker-Blom

July/August, xii + 324 pp., £20.40 (UK only)/\$49.00, 0.12.553120.6

Expression of Eukaryotic Viral and Cellular Genes contains recent and important papers by some of the most prominent molecular biologists in the world. There are articles about the structure of viral genes. (For example adenovirus, influenza virus and alphaviruses); The expression of viral genes (For example SV40 and adenoviruses, vesicular stomatitis virus and encephalo-myocarditis virus (EMC)); mechanism of translation of capped viral mRNAs: the structure and expression of transforming genes of RNA tumour viruses; the control of eukaryotic gene expression, including in vitro transcription of cloned ovalbumin genes, as well as cloning and expression of eukaryotic genes in heterotypic environments.

Handbook of Marine Mammals

Volume 1: The Walrus, Sea Lions, Fur Seals and Sea Otter

Volume 2: Seals

edited by Sam H. Ridgeway and Richard J. Harrison

Volume 1: July/August 1981, xvi + 236pp., £14.60 (UK only)/\$36.50, 0.12.588501.6.

Volume 2: September/October 1981, xvi + 350pp., 0.12.588502.4

Interest in marine mammals has much increased in recent years as our knowledge of them has grown. In particular, the large cetacean brain and their supposed superior intelligence over other animals, in conjunction with their obvious diving and swimming abilities, have made marine mammals fascinating creatures to study. With the aid of distribution maps, identification pointers and spectacular photographs and drawings, as much as is known of each animal about its biology and life history is reviewed, and its identifying characteristics and distribution described. Similarities and differences are stressed and some mention is made of economical and commercial aspects. A full bibliography is included for each chapter.

How Britain runs its science...

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2 x 3ft. guide offers a comprehensive survey of the administration of British science, showing the interlocking relationship between science, engineering and medical establishments. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England. In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

PRODUCT REVIEW

Fluorescence microscopes

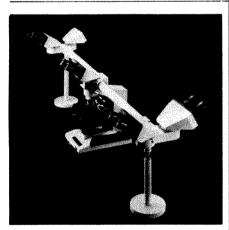

Among the new microscopes on display at Light Microscopy '81 will be the Fluoval 2, a research fluorescence microscope for incident and transmitted light fluorescence microscopy. This microscope from Carl Zeiss Jena Ltd. is suitable for most modern fluorescence microscopic techniques, including multi-staining. Another new microscope on display will be the incident and transmitted light microscope, Epignost 2E, which has long-working distance objectives and an image erecting tube for micro-assembly and micro-quality control work.

Circle No. 100 on Reader Enquiry Card.

Flatfield optics

A SERIES of new microscopes featuring DIN Micro Plan optics has been produced by Swift Instruments, Inc. These microscopes have standard features such as a clutch mechanism that operates automatically to prevent damage to the finely-balanced gear train, and a stage that is raised uniformly on precision ball bearings. The model M973-DM also features research-calibre DIN flatfield Micro Plan optics and a choice of centerable DIN condensers. The Swift DIN Micro Plan objectives are designed to give a flatter field and better resolution.

Circle No. 101 on Reader Enquiry Card.

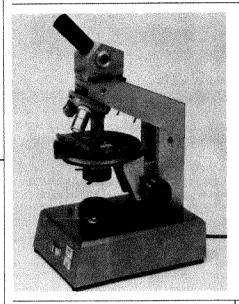

Multi-viewing attachment

AUNIT for multi-viewing, the MDO, is now available from Olympus for use with the new BH2 series microscope and others in the range. The MDO allows up to five observers to simultaneously view the same specimen. The image for each user is of equal brightness, with the same magnification and orientation as the one seen by the instructor. The modular design of the MDO allows for a comfortable working distance between each observer. Both brightfield and phase contrast observation are possible with this unit.

PRODUCT REVIEW - MICROSCOPY

The Light Microscopy '81 exhibition, organized by the Royal Microscopical Society, is being held at Imperial College, London, UK from 7 to 9 July. The notes on these pages include information provided by the exhibitors. For further details circle the appropriate number on the reader enquiry card bound inside the journal.

Polarizing microscope

A NEW polarizing microscope for both incident and transmitted light application is being introduced by James Swift. In the design of the MP81, particular attention has been paid to eliminating unneccessary controls while retaining full facilities and allowing easy servicing. The MP81 is available as a transmitted, incident or combined transmitted/incident light microscope. Both incident and transmitted light illumination systems use highintensity tungsten-halogen light sources. The MP81 features research standard objective centering, ball-bearing stage, a Bertrand-lens monocular, wide-field eveniece with cross-hair, solid-state brightness control and a range of accessory items.

Circle No. 105 on Reader Enquiry Card.

Stains

A RANGE of over 200 dry stains and dyes, 53 staining solutions and a comprehensive list of buffers in tablet or concentrate form is available from BDH Chemicals. Other materials for microscopy include embedding and mounting media and immersion oils. A new catalogue, 'Stains and Microscopy Materials', gives comprehensive details of the whole range and lists stains and dyes by colour index number for easy identification. The range of stains and microscopy materials will be on show at the Light Microscopy exhibition.

Circle No. 103 on Reader Enquiry Card.

SEM for research

A SERIES of scanning electron microscopes has been announced by Bausch & Lomb. The Nanolab 2000 and 2100 instruments offer ease of operation, with the following features: access to the stage from above; beam profiling function to give maximum performance and long filament life, and true TV imaging up to ×100,000 with precision stage. Both Nanolab instruments provide resolution to 60 Å with a standard tungsten emitter and an optional LaB, electron source increases resolution attainable to 40 Å. The Nanolab 2100, designed specifically for research, allows continously variable accelerating voltage, dual magnification, 360° scan rotation, and a 2,500-line recording CRT. The Nanolab 2000 series has applications in metallurgy, quality control, electronics, geology, forensics, biology and medicine.

Optics accessories

VARIOUS products from Anaspec will be shown at Light Microscopy '81, including optical microspectsometers, fibre optic data multiplexers, optical monochromators, diffraction gratings, and a complete range of TV facsimile transmission systems, image digitizers and slow scan

Circle No. 106 on Reader Enquiry Card.

Illumination systems

A BULLETIN from Dolan-Jenner Industries provides detailed specifications for their fibre optic illumination systems. As fibre optics transmit mostly visible light from an incandescent source, they act as heatabsorbing filters and provide cool light at the point of application. Several systems are illustrated, including single and dual branch, and annular configurations. Mounting stands, lenses and adapters for various microscopes are also described. A series of rigid miniature probes to supply illumination to difficult areas is also available. Charts are included to show working distance with and without lenses. Circle No. 107 on Reader Enquiry Card.

Image analysis

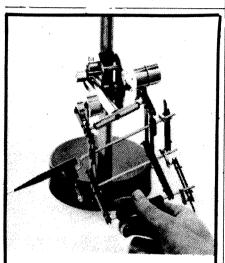

ONDISPLAY at Light Microscopy '81 will be an image analysis system from Graphic Information Systems Ltd. This system can quantify the constituent parts of microscopic images either directly from a light microscope or from a photograph.

Circle No. 108 on Reader Enquiry Card.

Histology

PRODUCTS relevant to semi-thin resin work are included in a new catalogue from Emscope Laboratories Ltd. This catalogue covers fixative reagents, processing solvents, embedding kits, resins and components, laboratory chemicals, light microscopy stains (dry and in solution), enzymes, mounting media and a new range of embedding, processing, sectioning and staining accessories.

Circle No. 109 on Reader Enquiry Card.

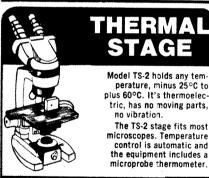

SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.

A varied range available. All simple to operate.

Fault detection

INTENDED specifically for semiconductor industry, the Polyvar 66 microscope from Reichert-Jung is not only suitable for research applications, but can also be used for monitoring production processes. It is designed to accept a large interchangeable mechanical or motor stage with a specimen traverse range of 6×6 inches, and has an integrated, fullyautomatic camera system which makes hard copies of the image. The modular system of the Polyvar-Met 66 allows various techniques, such as viewing of overall structural/mechanical faults and examination of photochemical coating faults, to be selected and operational within seconds. The module required is plugged into the microscope stand.

Circle No.110 on Reader Enquiry Card.

Light microscopes

MICROSCOPES intended for life and materials sciences will be shown by Carl Zeiss at Light Microscopy '81. These will include stereoscopic, inverted, industrial and axiomat modular microscopes, plus accessories for fluorescence, polarizing microscopy, photomicrography, photometry, image analysis and interference microscopy.

Circle No.111 on Reader Enquiry Card.

50 Å scanning

A NEW scanning electron microscope, the model JSM-35CF from JEOL, will resolve 5 nm (50 Å) by using a new 'corrected field' objective. The instrument has an improved electron gun design to give a high quality image. Most laboratory sites will achieve 4 nm (40 Å) resolution with the standard tungsten hairpin emitter. An alignment wobbler allows rapid adjustment of the objective aperture, particularly important for high resolution results and for probe work with optional wavelength and energy dispersive detectors. The precision specimen stage is designed to take heavy specimens and will reset to position coordinates x, y, z, rotation and eucentric tilt to very high accuracy. Optional extras include split-screen imaging, scan rotation, derivative processing and alternative recording cameras.

Circle No.112 on Reader Enquiry Card.

Slides and stains

A WIDE range of prepared microscope slides is available from Griffin and George Ltd. The sets contain selected slides for study of parasitology, protozoa and algae, for example. Griffin and George also supply a range of zoological, botanical and histological microscope stains.

Circle No.113 on Reader Enquiry Card.

Motorized micrometers

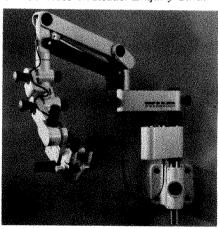

HIGH precision motorized and manual translation stages, rotators and optical mounts are available from Oriel Scientific. These include both stepping motor driven units with step size of 1 μ m, and d.c. motor units — the Motor Mike actuators. These are motorized micrometers which can replace the manual micrometers found in most stages and rotators. Control units are available for all drives.

Circle No.114 on Reader Enquiry Card.

Surgical microscopes

Even the finest and lowest-contrast details can be clearly seen using the M600 series of surgical operating microscopes from Wild Heerbrugg. They provide a large, evenly illuminated field of view of striking depth. These instruments can be placed in any position with mm accuracy and have a considerable range of height adjustment. A continuously variable counterbalance allows the instrument to be guided with ease and precision, even with a ciné camera attached. Thus, the instrument can be adapted for uses such as photomicrography, filming or recording on videotape.

Circle No.115 on Reader Enquiry Card.

Specimen preparation

A NEW product in the field of specimen preparation, the Polycut, will be shown at the Light Microscopy '81 exhibition. This heavy-duty microtome from Reichert-Jung is suitable for sectioning hard and/or large biological specimens and a wide range of industrial materials.

Modular interactive automatic image analysis system

- Image memory and array processor specifically designed for image analysis
- Fully software orientated with programmes for image processing and geometric analysis
- Full range of image inputs ie SEM,PHOTOMETER, TV and output interfaces including DMA
- Image memory expandable from 512 x 512 picture points to 4096 x 4096.
- Access to any picture point for binary or multiphase processing
- Image editing etc, via digitising tablet for faster more accurate discrimination
- Capability to measure in semi-automatic mode.

RNA Sequencing Enzymes

Eliminate side reactions; use P-L Biochemicals' proven quality sequencing grade enzymes. Tested under actual sequencing conditions.

RNA Sequencing kit 200 units each of Ribonucleases: Phy M, B. cereus, T1, and U2

0998 Expanded RNA Sequencing kit Contains the enzymes in 0977 plus dephosphorylated RNA sequencing standard, digestion buffers, carrier tRNA, alkaline hydrolyses solution and procedure sheets

0994 Ribonuclease Phy M (A+U specific)

0993 Ribonuclease B. cereus (U+C specific)

0991 Ribonuclease T₁ (G specific)

0992 Ribonuclease U2

(A specific) **RNA** Ligase 0880

(RNase free) For 3' end-labelling 0734

Polynucleotide kinase (Nuclease free) For 5' end-labelling Call or write for complete information

X-RAY **MICROANALYSIS** IN BIOLOGY

Edited by M.A. HAYAT

Professor of Biology at Kean College of New Jersey

June 1981; £30.00; 500pp; ISBN 0 333 32355 6

CONTENTS

Principles and Instrumentation — A.T. Marshall; Preparation of Specimens: Changes in Chemical Integrity — A.J. Morgan; Frozen-Hydrated Specimens — A.T. Marshall; Frozen-Hydrated Sections - A.T. Marshall; Sections of Freeze-Substituted Specimens - A.T. Marshall; Influence of Specimen Topography on Microanalysis — F.D. Hess; The Skeletal Muscle — M. Sjostrom: Liquid Droplets and Isolated Cells -J.V. Bonventre, K. Blouch and C. Lechene; Quantitative X-Ray Microanalysis of Bulk Specimens — F.D. Ingram and M.J. Ingram; Quantitative X-Ray Microanalysis of Thin Sections - G.M. Roomans; Index.

This is the first book dealing exclusively with x-ray microanalysis of biological specimens. It not only presents the basic theory and operation of the instruments used for producing, measuring and interpreting x-ray signals, but also describes in detail the preparation of bulk specimens, sectioned specimens and fluid specimens.

The book includes both qualitative and quantitative analysis of biological materials and it discusses application of x-ray microanalysis to pathology, physiology and cytochemistry.

Instrumentation is presented in a concise manner and methodology in detail. Almost all instruments are covered, including TEM, SEM and STEM. Instructions are given on how to produce, measure and interpret x-ray signals and emphasis is given to the aspects of instrumentation that are of practical use. In its comprehensive compilation of methods for preparing biological specimens the advantages and disadvantages of alternate methods are discussed.

READERSHIP: Electron Microscopy, Biology, Biochemistry.

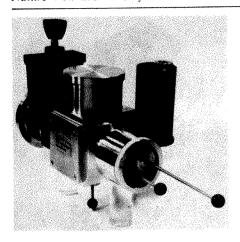

LEVEL: Undergraduate and graduate students. researchers and research technicians.

Send your orders, requests for further information etc. to: FRANCES ROACH, SCIENTIFIC AND MEDICAL DIVISION, MACMILLAN PUBLISHERS LTD. HOUNDMILLS, BASINGSTOKE, HAMPSHIRE **RG21 2XS.**

Cryo system

THE Hexland Cryo system includes an efficient cold stage, specimen sublimation and preparation facilities for in situ evaporation, sputtering, cutting/fracturing, and sublimation. The Cryo system can be interfaced to most scanning electron microscopes, and consists of modular units, including a cryogenic stage, capable of maintaining temperatures of - 190°C or better for long periods. A decontaminator can be located above the specimen. This cold finger/plate is connected to an independent dewar, and will maintain a temperature similar to that of the cold stage, thus making it an efficient decontaminator. A Cryo pre-chamber fitted to the SEM allows the specimen to be transferred from the cooling chamber, cryotome or the Hexland slushing chamber to the cold stage. The pre-chamber has a specially designed cold block with its own liquid nitrogen dewar, accurate thermocouple and a heater for sublimation. The specimen can be prepared in situ in the prechamber, which has fracturing facilities, a cold knife, a viewing port, optional stereo viewer and variable specimen height control. A small vacuum anti-chamber allows the specimen to be transferred from the Cryo slushing chamber to the prechamber. During this process, the antichamber can remain under vacuum to prevent the specimen coming into contact with the atmosphere. The slushing chamber has a cover and argon/nitrogen bleed valve for rapid freezing of the specimen to - 210°C.

Circle No. 117 on Reader Enquiry Card.

System microscopes

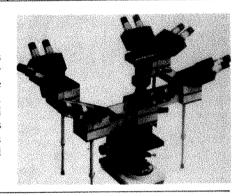

Easy viewing by means of an observation tube inclined 30° to the horizontal is possible using a new design of microscope from Olympus. The focusing knobs allow smooth, light movement and are positioned low to enable the hands to rest naturally during operation. To allow easy processing of a large number of specimens, the stage is in a low position. Ultra-low magnifications ($\times 1$ to $\times 4$) are possible using a new condenser and the illumination system allows observation under Köhlertype illumination from $\times 1$ to $\times 100$. The most advanced model in the series has the unusual feature of compensation for changes in supply voltage, maintaining a constant level of brightness.

Circle No. 119 on Reader Enquiry Card.

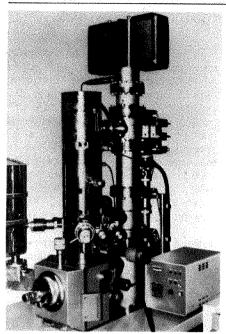

Teaching microscope

THE conference microscope, Balplan, from Bausch & Lomb is available in models with up to seven heads for teaching or conference situations. Designed to save space while allowing comfortable viewing, Balplan delivers crisp, bright images to all seven heads. Balplan Conference models are also available in 2, 3, 4 and 5-head configurations for both brightfield and phase contrast applications.

Circle No. 118 on Reader Enquiry Card.

LIGHT MICROSCOPY '81 — THE STATE OF THE ART International Conference and Exhibition on Light Microscopy Imperial College, London SW7 7-9 July, 1981 The Exhibition, is organised by the Royal Microscopical Society in association with 'Nature'. The Conference not only marks the inauguration of the Light Microscopy Section of the Royal Microscopy as it is now and of significant developments. The first day's programme is devoted to the instrument itself. The second day is concerned with imaging techniques, and "light" microscopy is interpreted liberally. The third day will deal with two aspects of measurements on images — photometric (in transmission, emission and reflection) and geometric. EXHIBITION In conjunction with the conference, there will be an exhibition of the latest products of the Light Microscope Manufacturers. This exhibition will be open, free of charge, to registrants and non-registrants. Times for non-registrants to visit the exhibition will be open, free of charge, to registrants and non-registrants. Times for non-registrants to visit the exhibition betails available from the Administrator: THE ROYAL MICROSCOPICAL SOCIETY 37/38 St. Clements, Oxford OX4 1AJ Telephone: Oxford (0865) 48768/721081

SEM system

A NEW lanthanum hexaboride (LaB_c) system for the DS-130 scanning electron microscope (SEM) is now available from International Scientific Instruments. It has a filament life of 500 h, although filaments have been known to last for > 1.000 operating hours. The DS-130 guarantees 30 Å resolution and is microprocessorcontrolled. The option of the LaB, system further enhances its capability for low voltage work in spatial modes such as backscattered electron imaging, cathodoluminescence and microanalysis. It is intended particularly for research on the surface of materials or for fragile or nonconducting specimens. Changeover from tungsten to LaB, emitter is at the touch of a button. This new system overcomes previous problems of short filament life and poor stability of LaB₆ emitters. A suitable vacuum level is obtained by either an ion or turbo pump.

Circle No. 120 on Reader Enquiry Card.

Photomicrography system

DEVELOPED for situations where automatic exposure metering is not required, the PFX System from Nikon is a manually-operated photomicrographic instrument with a direct projection optical system. The vibration-dampened, leaf-type shutter operates at speeds of 1/250th to 1 s with positions for bulb and time. A new ×2 ocular viewfinder or photomask eyepiece allows accuracy of focusing. Almost 100% of the light is available to image the film during exposure by the direct projection optical system. This is achieved by eliminating all relay lenses, prisms and reflective surfaces in the optical path. Thus, film images have greater contrast, sharpness and improved colour fidelity. The FX 35 manual camera back is standard for 35 mm applications.

Circle No. 121 on Reader Enquiry Card.

Heating/freezing stage

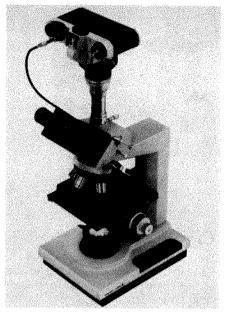

CHANGES in the properties of a wide range of materials can be observed in controlled conditions of heating and cooling using a compact apparatus developed by Stanton Redcroft. Two versions of the transmitted light heating/freezing stage (TLHFS) are available, one operating from the low temperature of -180°C to 550°C; the other from ambient to 600°C. Intended for use with any high quality microscope using long-working distance objective lens, the apparatus permits light to pass through the material under test by resting the sample on a sapphire window; this allows the characteristics of a material to be examined more fully than is possible with hot/cold stages using reflected light. Use of a polarized light source allows additional data to be obtained from materials such as organic polymers, pharmaceuticals and inorganic materials. An applications note on transmitted light hot stage microscopy can be obtained by circling the appropriate number on the reader enquiry card.

Circle No. 122 on Reader Enquiry Card.

Precision measurement

PRECISION measuring equipment from Vickers Instruments will be shown at Light Microscopy '81, including the M41 image shearing microscope with coincidence setting shear. Also on display will be a precise focus indicator which allows focusing of the M41 by bringing two images of a graticule line into coincidence. A range of conventional microscopes is also available, including the M16.

Triocular microscope

FOR USE in routine clinical laboratory tests. Bausch & Lomb have recently introduced the Galen II microscope, which also has applications in veterinary and medical schools. The Galen II features monocular, binocular and triocular heads with optional 35mm camera kit, exclusive dual diopter adjustments, and front-mounted illumination controls. Also available are a wide range of flat-field achromatic, planachromatic or phase contrast objectives, plus phase contrast and polarizing accessories. Optional accessories include a darkfield condenser, a choice of tungsten or tungsten-halogen illuminators, and various eyepieces.

Circle No. 124 on Reader Enquiry Card.

Stereoscan

THE Stereoscan 100 scanning electron microscope from Cambridge Instruments Ltd. has a wide range of uses but is particularly suited to routine applications. It is simple to install and use, compact and designed for ease of operation. The specimen chamber has internal measurements of $170 \times 270 \times 280$ mm, allowing 90° tilt on 127 mm-diameter specimens. This means that a wide range of specimens can

be studied intact. The Stereoscan 100 is capable of 70 Å resolution combined with a magnification of × 25 to × 200,000. It has a wide range of accelerating voltages (2, 3, 5, 10, 15 and 25kV) and low voltage option (0.5, 1, 2.5, 10 and 25kV). The ultra-clean vacuum is turbomolecular-pumped and operator aids include a choice of two automatic recording systems, TV and a wide range of slow-scan speeds. A large 9-inch viewing screen can be tilted to suit different operators.

AT I OUT CEMEL TS

Awards

The Artois-Baillet Latour Health Prize—has been awarded to **Professor Sir Cyril Astley Clarke**. Sir Cyril has also recently been awarded the Linnean Society Medal 1981 for Zoology.

The government of France has named Lawrence Berkeley Laboratory scientist **George Brecher**, to the French National Order of the Legion of Honor for his work in haematological research.

I. I. Rabi of Columbia University is to be awarded the Michael I. Pupin Medal.

The prizewinners of the Feldberg Foundation awards for 1981 are **Prof. Lindemann** University of the Saarland; **Prof. J. Hughes** (Imperial College of Science and Technology London); **Prof. H. Kosterlitz** (Unit for Research on Addictive Drugs, University of Aberdeen).

Thomas Fryer (NASA's Ames Research Center) has been named NASA Inventor of the Year for 1980 for his work in medical electronics.

Winners of Brandeis University's 1981 Rosenstiel Award for "Excellence in Basic Medical Science Research" are Bengt I. Samuelsson (Karolinska Institute in Stockholm) and Elias J. Corey (Harvard University) for related research of substances that influence the body's vital organs; and Frank H. Westheimer (Harvard University) for contribution to research in biochemistry.

In recognition of fundamental work in the field of crop bioenergetics the Rank Prize funds have been awarded to: Dr Hugo Peter Kortschak; Dr Marshall Davidson Hatch, and Dr Charles Roger Slack.

Applications are invited for the Institution of Chemical Engineers Industrial Research Fellowship which carries an Honorarium of £1,000 and necessary travelling expenses. The Fellow will be expected to produce a report identifying recent advances in the subject and highlighting areas where future research would be beneficial. Applications to: Mr S.A.E. Buxton, Senior Assistant Secretary (Technical), The Institution of Chemical Engineers, 165-171 Railway Terrace, Rugby, UK.

The Fondation de Physiopathologie Professeur Lucien Dautrebande will award his next prize of about 1,500,000 belgian fr during 1982 for work on human or animal clinical physiopathology having therapeutic implications. Further information from the office of the Foundation, 35, chaussée de Liège, 5200—Huy, Belgium.

For the John Eggert Prize Foundation. Young scientists are encouraged to submit papers from the field of Imaging Science to Dr W. F. Berg, Hellstr. 7, DH-8127 Forch, Switzerland by 15 October 1981.

The British Vacuum Council seeks to encourage young scientists (under 27 years of age) by inviting entries for its annual C.R. Burch Prize of £100 for the best submitted paper on vacuum studies, surface science, thin films, or any related topic in which vacuum science or engineering plays an important role. Entries by 1 October 1981 to: Dr J.S. Colligon, Department of Electrical Engineering, University of Salford, Salford, UK

The Peter Debye-prize will be awarded by the University of Limburg, to a person or group of persons who are considered to have made a fundamental contribution to research in the field of immunology and oncology. Further information from the University of Limburg att. Drs V. H. Rutgers, secretary of the jury, Tongersestraat 53, PO Box 616, 6200 MD Maastricht, The Netherlands.

Appointments

Professor Max Whitten, Professor of Genetics at the University of Melbourne has been appointed Chief of CSIRO's Division of Entomology.

Dr. Angus D. McEwan has been appointed Chief of the CSIRO's new Division of Oceanography, he is currently a research leader in the Division of Atmospheric Physics.

Lord Todd, (Christ College, Cambridge) and Professor Thomas (University of Cambridge) have been elected Honorary Fellows of the Indian Academy of Sciences.

Meetings

8-10 August, Cryogenic Process Engineering, San Diego (CRYOCOURSE, PO Box 3081, Boulder, Colorado 80307, USA).

10-14 August, **1981 Cryogenic Engineering** Conference, San Diego (Dee Belsher, CEC, NBS, 1-4001, Boulder, Colorado 80303, USA).

17-22 August, **High Pressure in Research** and **Industry**, Uppsala (High Pressure Conference, c/o RESO, Box 1313, S-75143 Uppsala, Sweden).

31 August — 2 September, **British** Association Annual Meeting, York (Press Office, BAAS, 23 Savile Row, London W1, UK).

2-4 September, Uranium Institute Annual Symposium, London (Conference Associates UIS, 34 Stanford Rd, London W8, UK).

7-10 September, **EMAG '81**, Cambridge (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

9 September, **Asthma**, London (Society for Drug Research, c/o Institute of Biology, 41 Queen's Gate, London SW7, UK).

10-11 September, Concepts of Purity, Canterbury (Mr P.R.W. Baker, Wellcome Research Laboratories, Langley Court, Beckenham, Kent, UK).

10-21 September, Leukotrienes and Prostacyclin, Erice (Prof. F. Berti, Istituto di Farmacologia e Farmacognosia, Universita di Milano, Via Vanvitelli, 32, 20129 Milano, Italy).

13-16 September, Surviving the 80s, Southampton (Conference 1981, Southern Science and Technology Forum, Building 25, The University, Southampton, UK).

14-15 September, Integrated Optics, London (The Institution of Electrical Engineers, Savoy Place, London WC2, UK).

17-18 September, AGU Pacific Northwest Regional Meeting, Ellensburg (B. Bentley, PNAGU, Central Washington University, PO Box 1000, Dept of Geology, Ellensburg, Washington 98926, USA).

17-18 September, AGU 1981 Midwest Meeting, Minneapolis (Agu Midwest Meeting, 2000 Florida Ave, NW, Washington DC 20009, USA).

19 September — 2 October, Postgraduate Course on Pain Therapy, Vicenza (Agenzia Spiller, C.so Felice 151, 36100 Vicenzia, Italy).

20-25 September, Computer Ergonomics, Loughborough (HUSAT, Dept of Human Sciences, University of Technology, Loughborough, Leicestershire, UK).

21-23 September, **Turbulence**, Missouri-Rolla (Prof. G.K. Patterson, Chemical Engineering Dept, University of Missouri-Rolla, Rolla, Missouri 65401, USA).

21-24 September, Gas Fluidisation, Bradford (Mr D.B. Firth, I Chem E, 12 Gayfere St, London SW1, UK).

21-25 September, Clean Air and Pure Water — Tomorrow's Luxuries?, Jönköping (Elmia AB, Box 6066, S-550 06 Jönköping, Sweden).

22-25 September, Information '81: Forecasts and Realities, Oxford (ASLIB, 3 Belgrave Square, London SW1, UK).

22-23 September, Applications of Petroleum Geochemistry to Basin Studies, London (Dr J. Brooks, Exploratino Dept, The British National Oil Corporation, 150 St Vincent St, Glasgow, UK).

29 September — 2 October, Indoor Pollution, Health and Energy Conservation, Amherst (Mrs J. Curhan, Energy and Environmental Policy Center, John F. Kennedy School of Government, Harvard University, Cambridge, Massachusettes 02138, USA).

QUEEN MARY COLLEGE University of London LECTURER IN ZOOLOGY

Applications are invited for this post in the Department of Zoology and Comparative Physiology. Preference be given to applicants specialising in vertebrate zoology although specialists in other fields will be considered.

Salary on scale £6,070 — £12,860 pa plus £967 London Allowance.

Forms and further details available from The Secretary, (N) Queen Mary College, Mile End Road, London E1 4NS, to whom applications should be (8948)A made by 31 July 1981.

IMMUNOLOGIST MOLECULAR BIOLOGIST

Postdoctoral positions available for 1) Molecular genetic studies of expression of immunoglobulin genes, and 2) for characterization of lumphocyte subpopulations as identified with monoclonal antibodies and separated by FACS.

Send curriculum vitae and names of three references to: K L Knight, PhD, University of Illinois Medical Center, SBMS Microbiology/Immunology, 835 South Wolcott, Chicago, IL 60612.

An Equal Opportunity/Affirmative Action Employer. (NW727)A

UNIVERSITY OF **CAMBRIDGE CELL BIOLOGISTS**

Interested in postdoctoral work on cell surface properties and biochemistry, in situ nucleic acid hybridisation or electron microscopy required for projects on mammalian embryos.

Applications, with names of three referees, by 31st July, to: Dr M H Johnson, Department of Anatomy, Downing Street, Cambridge

(8982)A

INSTITUTE of Cancer Research: A Research Assistant is required to join the Leukaemia Unit at Sutton, Surrey, to investigate the immune status of patients receiving bone-marrow transplants. Previous experience in cell culture and mixed lymphocyte cultures essential. Salary in scale £4,677 — £6,222 pa plus London Allowance of £527 pa. Applications with a full CV (in duplicate) and the names of two referees should be sent to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/6.

(8990)A

Biochemists/ **Biotechnologists**

the world's foremost organisations dedicated to all aspects of new product and process development, with laboratories in the UK, Australia, Belgium and the USA and covering almost every scientific and engineering field.

Continuing expansion has created new vacancies in the field of biochemistry. Candidates will have a good first degree in biochemistry, preferably with a Ph.D. Expertise in the synthesis of enzymes, nucleotides, peptides or other related biochemicals will be an advantage.

Applicants should also be creative, adaptable and commercially aware. Experience in a commercial biochemical environment would be a decided asset.

Please write with career details to: Dr. R. C. Whelan, Operations Director, Patscentre International, Melbourn, Royston, Herts, SG8 6DX. Tel: Royston (0763) 61222.

Patscentre International Cambridge Division

(8979)A

GRIFFITH UNIVERSITY Brisbane, Australia

LECTURER -SCHOOL OF SCIENCE (Life Sciences - Plant Molecular/Cellular Biology)

A Life Science option is offered by the School of Science and includes an integrated coverage of Genetics, Microbiology and Physiology.

Applicants should possess appropriate experience in plant biological sciences, relating to molecular and/or cellular aspects. Depending on the expertise of the appointee, the main teaching duties will be in undergraduate courses in plant physiology (second year course), genetics, and microbiology (second and third year courses). It is anticipated that there will be opportunities to teach honours level courses. Pursuit of research is a requirement of the appointment and collaboration in group and interdisciplinary research projects is encouraged.

It is anticipated that the appointee will commence duties as early as possible in 1982. Apointment will be made at the lower end of the Lecturer scale, ie \$A19,821 - \$26,037.

Further details may be obtained from the School Administrator, School of Science, Griffith University, Nathan, Queensland, Australia, 4111, to whom applications (including curriculum vitae, names and addresses of two referees) should be sent by 31 August 1981.

Conditions of appointment and application procedure also available from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H (8964)A

HOWARD READ

CORRESPONDENCE

K. PAULUS

Continued from p. 8

This is not the ideal test of "survival of the fittest"; it does not compare fitness and survival within one population. Instead, it compares populations, of which the later is descended from survivors of the earlier (at both the individual and the species level). The populations are separated by some millions of generations; this interval is long enough for comparison of the populations with an objective standard to reveal an increase in fitness. Could this cumulative increase in fitness be produced by anything except "survival of the fittest"?

D.G. STEPHENSON

Department of Geology. University of Keele, UK

- Rudwick, M.J.S. Br. J. Phil. Sci. 15, 27-40 (1964). Paul, C.R.C. in Patterns of Evolution (ed. Hallam, A.),

University staffing

Sir - On behalf of my members I should like to make comment on the article, "Change wanted" in Nature of 11 June (p.442).

I do not wish to proffer an opinion on the second interim report from the Swinnerton-Dyer committee but I do want to protest most strongly about your suggestion that a cutback in non-academic staff would be quicker and should be considered first.

First, the financial savings accrued from such cuts would be a drop in the ocean in comparison with the salaries saved from the academic staff. We as technicians are aware of departments with an academic staff establishment which in no way reflects the actual number of students taught. It is the topheavy nature of such departments that needs careful consideration.

Second, the last sentence in the article asks "But is not the university an institution whose chief purpose is academic?". In order to maintain that purpose the academics need the back-up services of trained technicians to provide an efficient lab class and assist with research projects. An academic with a heavy teaching load trying to do research at the same time would either have to cut back the amount of teaching or give up a substantial part of his research projects in order to replace the technical services now provided.

As regards cleaners and porters, they already work in rather grubby conditions and I am sure that academic standards would not be improved if the academics had to clean their own rooms or provide an adequate supply of toilet paper in the lavatories.

In conclusion, we are aware that because of government cuts, savings must be found somewhere. But please do not point the finger at one group of staff. Far rather let each college put its own house in order and safeguard the jobs and careers of all its employees by looking at other areas of saving

The universities could also make a positive and voluble stand against the government cuts in an effort to maintain the opportunity of higher education for as many people as possible.

A.L. PRICE THOMAS

Branch Chairman, Association of Scientific, Technical and Managerial Staffs. Westfield College Branch, London NW3, UK Psychiatry on trial

Sir - Your ill-disguised dismissal of R.D. Laing (Nature 4 June, p.367) does little to clarify the many interconnected issues raised by the Sutcliffe case. Permit me to draw the following lessons from his trial:

(1) Escape into the protection of some illness, however well-defined or spurious, is no longer possible. Each of us needs to accept responsibility for our actions.

(2) The utter "normality" displayed by Sutcliffe during his trial now puts the onus on psychiatry to defend its labelling of unacceptable behaviour as "illness": may I remind you that there are psychiatrists amongst those who collude in the incarceration of Soviet dissidents.

(3) That anyone, particularly psychiatrists, should be surprised when the "common and pervasive" sexual abuse of, and violence towards women takes such an extreme form, is but a sad reflection on our society. Where I beg to differ from you is in not ascribing this to "psychiatric illness" but rather to the inevitable consequence of a pervasive morality. The sooner we stop hiding behind the comfort of psychiatric illness the better we shall see our own responsibility as members of the society that has nurtured Sutcliffe.

Clifton, Bristol, UK

Search for truth

SIR - Although not directly involved in the investigation of the origin of species, astronomers are, nevertheless, involved at the "sharp end" of research into origins as they seek to explore the Universe and as such I would like to comment on the leading article "How true is the theory of evolution? (Nature 12 March, p.75).

Darwin's theory of evolution, like the theory of special creation, is just that, a theory, which is incapable of being proved as fact by scientists, and also incapable of being falsified. Both theories therefore, if given the label of scientific theories, fulfil Popper's second criterion. Second, in order to assemble and evaluate evidence for particular theories, scientists, hopefully, try to be as objective as they possibly can; if not, then their credibility may well be called into question. However, most people would find it impossible to be totally objective and impartial in weighing up evidence. Each of us has prejudices which we are incapable of putting out of our minds as we seek to assess observed facts, so their interpretation can never be fully objective.

This problem is particularly acute when the origin of the species is being investigated. The whole question of the existence of God and as a consequence our accountability to him as God, past conflicts between church leaders and scientists, dissatisfaction with the implications of evolution on the one hand and with the role of the Bible and the church on the other have all made the investigation of the origin of the species a good deal more subjective than other areas of scientific investigation.

Creationists will do themselves a great disservice by choosing to bury their heads in the sand as scientific investigation proceeds in the future but equally so will evolutionists if they draw up behind a barrier of indignation at the thought of Darwin's theory never

achieving the status of fact.

Objectivity of investigation and interpretation is not only desirable but very necessary, for in the final analysis the truth will stand all investigations and still be the truth long after we are all laid to rest.

Department of Astronomy,

University of Manchester, UK

American Creation

SIR - The correspondence arising from the British Museum's cladistic activities has had one common aim — to avert the imminent threat of an upturn in creationism (Jukes, Nature 21 May p.186; editorial 28 May p.271). We are tempted to ask why evolutionism feels threatened by creationism, when the real controversy has not yet been stated openly. This does not lie in E. O. Wiley's question (Nature 30 April, p.730) "Does the phenomenon of evolution occur?", since the majority of creationists would not deny that evolution occurs, but in the question "Did the evolutionary mechanism provide the actual pathway from sterile Earth to living world?"

Any view of origins that does not invoke a supernatural Creator must conclude either that it did or that life arrived from space in some form, as proposed by Crick and Orgel, Wickramasinghe and Hoyle, and others. Either view must be accepted by faith, either in the propositions themselves or in the ability of science to provide proof in the future. The atheist, whose metaphysical presuppositions do not allow him to countenance any form of divine activity, is more close-minded than many theists, who would happily accept either theory or the alternative, special creation.

To take a narrower view, any survey of Bible-believing Christians would reveal a wide spectrum of conclusions. These would range from those who believe that God has worked through essentially neo-Darwinian evolution, to those "creationists" who find current evidence for Darwinian evolution unconvincing and conclude that special creation is consisten; not only with the scientific evidence but also with the whole of Scripture, the reliability of which can be verified experientially by the Christian.

It is often stated that many creationists take no account of the scientific arguments for evolution. Since the converse is also true, we will point to some of the issues we consider relevant. It is reasonable to point out that no plausible theoretical model exists which provides a mechanism for the spontaneous generation of nuclesc acids as informational macromolecules specifying polypeptides which themselves mediate the replication and expression of that information. The experiments demonstrating the formation of a variety of organic molecules from presumptive prebiotic soups fall far short of providing a pathway for chemical evolution. Again, it is self-evident that the fossil record leaves much to be desired and few biologists recognise the dependence of the geological column on radiometric dating methods based on questionable assumptions about initial conditions. The whole history of evolutionary thought is littered with the debris of dubious assumptions and misinterpretations, especially in the area of fossil "hominids". To come up to date, protein and DNA sequence data, generally viewed as consistent with an

evolutionary explanation of diversity, are invariably interpreted using methods which presuppose, but do not demonstrate, evolutionary relationships, and which use criteria that are essentially functional and teleological. Finally, there is a collection of isolated fragmentary pieces of evidence which are usually dismissed as anecdotal because they are irreconcilable with the evolutionary model. From the above and other considerations it is possible to argue a strong case for special creation.

If, however, we are to be banished to the lunatic fringe, we find ourselves in the company of men who are regarded as the founders of modern science - Boyle, Newton et al. These men formulated the laws of physics and chemistry, not by invoking the supernatural but by assuming it, in the conviction that all things were made by an intelligent and all-powerful Creator who had imposed order and meaning on his creation. So it seemed to them, and is it not reasonable to ask whether they would have begun to ask the right questions if it had seemed otherwise? It has, for example, been suggested by Needham that the reason for the failure of the Chinese to develop the scientific method of the West was that they did not see order in nature as ordained by a personal, rational being.

Science can be conducted only within a context or "world view" which inescapably determines its aims and directions. We, as scientists, must be aware that as long as our society looks to the great god of science for direction and meaning, our own world view will be shaped by our own science. If we assert untruth, half-truth or hypothesis as fact, society and we ourselves will be misled and we will be responsible for the cultural, political and ethical consequences. Truth was never determined by majority opinion.

We are dismayed by the methods and attitudes of American Creationism. The legislature cannot be used to establish truth, either scientific or spiritual. Furthermore we believe that the Bible, though accurate, was not written as a scientific textbook but written primarily to lead men to a personal knowledge of God through His Son. In that knowledge we are able to say: "By faith we understand that the world was created by the word of God" (Hebrews 11.3).

Chris Darnbrough John Goddard William S. Stevely

University of Glasgow, UK

Room for faith

Sir - Contrary to what your editorial on creationism and evolution might suggest (Nature 28 May, p.271), few "card-carrying believers" within the scientific community would hold to the "God of gaps" theory you describe. Few see any major conflict between science and religion. Most see them as providing different languages to describe the same phenomenon — the view that God created the world and that evolution was the mechanism by which he did it is not contradictory. "God created the world" cannot be held up as a scientific theory. It is scientifically and theologically unprovable. It has to remain a matter of faith. However, some of the corollaries of creationism: the insufficiency of mutation and natural selection to account for intra-specific diversity, catastrophic geology, a shrinking rather than an expanding active gene pool; are worthy of

some consideration within a scientific context. Indeed, it is surprising how rapidly some tentative theories in support of evolution have become scientific facts. The absurdity of recapitulation and the half-truth of horse evolution are still incorporated into school textbooks as irrefutable fact. Evolutionists often present their "beliefs" as dogmatic "fact" in a similar vein to creationists.

What is required is not that creation should gain equal time within the school curriculum of Arkansas or the exhibitions of the British Museum (Natural History); but that school pupils and general public alike are presented with the solid facts as far as they are known with both their limitations and their certainties (but not with conjecture or extrapolation). And that they be encouraged to draw their own conclusions; to observe the data, to construct their hypothesis and to test it against the new data as they emerge. In other words, they should be encouraged to learn and apply the scientific method. This should be the basis of all biology courses and museum exhibitions.

However, the controversy will not be stayed by the application of scientific method; because what one believes about the origin of life and of man has a grave effect on how one treats fellow man and how society functions.

NEIL K. MCBRIDE

Microbiology Department, Queen Elizabeth College, London W8, UK

Missing links

Sir — In your leading article "How true is the theory of evolution?" (*Nature* 12 March, p.75), you discussed the apparent inability of the Darwinian theory of evolution controlled by natural selection to explain the episodic nature of the fossil record.

It must be accepted that the fossil record of most evolutionary lines does indeed show changes taking place in discontinuous jumps rather than in a continuous manner. It is important to realize that even a continuous development resulting from the accumulation of many small changes may only rarely show itself as this in the fossils unearthed.

We are unlikely to find the fossil remains of more than one in a hundred million or so individuals. Most of the fossils which we see, therefore, are necessarily those of organisms which were common over large areas and which remained common and unchanged for long periods. For this to be possible the species concerned must have been well adapted to a particular niche in a stable environment. If the environment changes the niche must change, and may then be invaded successfully by another species, or even vanish altogether.

Once a species has filled a stable niche it can rarely gain by changing in anything but minor ways. In an environment which has been stable for a long time, all major neighbouring niches are likely to be filled by other successful organisms, so that individuals that differ from the species optimum are likely to be less successful than the norm. Natural selection will then act to slow down significant evolutionary change.

Rapid evolution can occur only where there is extremely intense intraspecific competition, as in the case of our own ancestors, or where a species is not well adapted to its habitat — for example in regions colder or wetter than the stable environment to which it was adapted, and/or with different fauna or flora. Population pressure in a successful species will constantly be supplying a trickle of individuals

to such non-optimal peripheral regions around the main habitat. In such a region a small mutation, useless or even mildly harmful, could be advantageous to survival outside the normal range. Again, this would be unlikely to help if the new area itself had a stable climax ecology where all important niches were already filled. It is in a small area with many empty niches, and perhaps cut off by some natural barrier introduced by climatic, volcanic or other phenomena, that a now nonoptimally adapted species may survive and find a whole series of minor mutations advantageous, eventually leading to major changes in structure and behaviour. During the whole of this development numbers will be limited, allowing a significant degree of genetic drift, and the intermediate forms may not persist for long, so that the chances of our finding fossils of such intermediates will be slight.

Not until the species has changed so much that it can successfully invade a new stable area when the barriers break down, as the rabbit did in Australia, can it become common and persistent over an extended period — and give us a chance to find its remains.

I am not trying to disprove the occurrence at some times in the past of large discontinuous jumps in evolution, or to prove that all evolution has occurred as a result of natural selection acting on a large number of random mutations, mostly small. All I am saying is that whichever of these is true the fossil record must be expected to be discontinuous.

"Missing links" may be truly missing, or simply so small in number and period of existence that they have not been found.

Department of Physics, University of Birmingham, UK

Scientists for sale?

SIR — Increasingly, the members of the biomedical research community are being forced to give their activities a greater immediacy of application. The commercial pattern into which the work on genetic engineering and monoclonal antibodies is falling reflects this pressure. There could arise conflicts in the academic mind some of which merit public discussion.

In the past there have been no constraints, other than moral, on the free movement of individuals between research groups. However, now, many of the commercially useful activities, whether in industrial or nonindustrial laboratories, involve team work. These groups, like football teams, require continuity for success and their members, it can be argued, should be subject to the same restraints on movement from laboratory to laboratory as are footballers between teams. Specifically, contracts of employment should be considered as not only binding on the employer but also on the employee. It could even be maintained that changes within the period of a contract could be arranged by mutual agreement but only on payment of an appropriate transfer fee. Breaking of the contract by either employer or employee should be subject to the process of the law in the usual way.

As things stand at the moment, poaching of staff and of ideas on which considerable development money has been spent can occur without let or hindrance. A.J.S. Davies Institute of Cancer Research, Royal Cancer Hospital, London, UK

The Queen's University of Belfast CHAIR OF CHEMICAL ENGINEERING

Applications are invited for the Chair of Chemical Engineering. The salary attached to the appointment is £17,676 per annum with contributory pension rights under FSSU or USS.

Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. Closing date: 18 September 1981. (Please quote Ref. 81/N) (8958)A

GUY'S HOSPITAL MEDICAL SCHOOL Renal Unit, Clinical Science Laboratories GRADUATE RESEARCH ASSISTANT

with experience in immunology and/or platelet work, required for one year for work on MRC supported research project.

Salary on scale £5,285 — £7,700, plus £967 London Allowance.

Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge SEI 9RT, quoting Ref. RM. Enquiries to Professor J S Cameron (Tel: 01-407 7600 ext. 2445). (8943)A

Public Health Laboratory Service Board Central Public Health Laboratory Food Hygiene Laboratory BIOCHEMIST

to join a small research group engaged in studies on the purification and characterization of various toxins associated with foodborne disease and to initiate studies on rapid methods for the detection of bacterial pathogens in food.

Applicants, male or female, should have an appropriate degree and post-graduate experience of a range of biochemical and immunological techniques; a higher degree would be an advantage. The successful candidate will be expected to show versatility and initiative to meet the future requirements of the laboratory.

The appointment will be at the Senior Microbiologist Grade. Current salary range £8,201 — £10,448 inclusive of London Weighting. NHS Terms and Conditions of Service will apply.

Applications, including full curriculum vitae and the names and addresses of two referees, should be sent to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT (Tel. 01-205 7041). (8961)A

Development Scientists-Recombinant DNA

Up to £10,000°

BUCKS

Amersham International Limited, formerly The Radiochemical Centre Limited, holds a major position in the development and supply of radioisotopes for research and medical applications. Many of our products are already used in molecular biology research and we have now set up a new group with the objective of investigating potential applications of recombinant DNA and developing new products.

We now have several attractive career opportunities for self-motivating and innovative scientists who have a strong background in one of the biological sciences and a good understanding and several years' practical experience of recombinant DNA techniques to help us meet these objectives.

One of the posts will particularly suit a scientist who has a thorough understanding of the application of radioisotopes in molecular biology and a background in biological chemistry plus research experience which has included handling and purifying nuclear acids and proteins.

Candidates must have an appropriate PhD qualification and a successful record of R & D work in an academic or industrial environment. Career prospects for the right candidates are very good in a British Company which has a world wide reputation and an excellent growth rate in a highly complex and competitive market.

Starting salaries will be up to £10,000* with the prospect of increases to £12,500+ and they will be reviewed in November. First class benefits will include full relocation assistance, where appropriate.

Please write with concise career details to P. L. Jones, Personnel Manager at the address below.

Amersham International Limited

Amersham

MIDDLESEX POLYTECHNIC RESEARCH FELLOW ROAD ACCIDENT STUDIES £6,960 — £10,929 pa inc

£6,960 — £10,929 pa inc (Burnham Researcher 'B' Scale) A temporary two-year post to carry out a research project into the effects of road improvement schemes on accidents, financed by the Science Research Council.

Candidates should preferably have a higher degree in a relevant subject—eg Civil Engineering, Mathematics, Statistics—with some experience of research in industry or in an institution of higher education. This post is not open to candidates who have previously held SRC funded Research Assistantships, but is open to those who have held SRC Studentships.

Write quoting ref A176C for post details, conditions of service and an application form, posting first-class to: Personnel Office, Middlesex Polytechnic, 114 Chase Side, London N14 5PN. For further information about the project, write to or telephone Dr C C Wright, Middlesex Polytechnic, Queensway, Enfield, Middlesex EN3 4SF. Telephone O1-804 8131 ext. 326. Closing date 13 July. (8946)A

UNIVERSITY OF BRISTOL Long Ashton Research Station HEAD OF PLANT SCIENCE DIVISION

An experienced plant physiologist or other plant scientist is required to lead and to manage the Plant Science Division, comprising work on environmental physiology, plant nutrition, plant biochemistry and growth regulation. The Division will need to collaborate extensively with others devoted to food and beverages, pomology and crop protection.

Appointment in the Deputy Chief Scientific Officer grade (at present £16,500 to £19,500 pa). Non-contributory superannuation scheme.

Essential qualifications are a Higher Degree and a well established reputation in relevant scientific disciplines. Furthermore, the post requires an understanding of the administration of research and the experience and personality to lead a team of approximately 38 expert staff.

This is a second advertisement; previous candidates will be considered without further application.

Further particulars from

The Secretary, Long Ashton Research Station, Long Ashton, Bristol BS18 9AF. Written applications, including a full cv, all relevant details and the names of three referees must be received by 24th July, 1981.

SYNCHROTRON RADIATION RESEARCH MRC/SERC JOINT APPOINTMENT

The Medical Research Council and the Science and Engineering Research Council have agreed jointly to appoint a Post Doctoral Research Associate to work at the SERC Synchrotron Radiation Source (SRS) at the Daresbury Laboratory. This appointment provides a unique opportunity for the right man or woman to make an original contribution to an expanding field of research. The successful applicant would be expected to take responsibility for supporting the exploitation of the SRS in the field of biological and medical applications of small angle x-ray scattering and to participate in the research programme. Projects already approved include work on proteins, muscle and viruses. and the appointee would be expected to act as a focal point for these activities and to advise and assist other SR users in this area. An experimental station is being commissioned and will be available for some of this work but the appointee would be expected to take part in the design, construction and operation of further equipment. For this reason, the appointee should have a good understanding not only of the application of SR to biological problems but also of electronic methods of x-ray detection and data collection. The ability to work as a member of a team and to have an enthusiasm for the development of new techniques are essential qualities.

An appointment will be made at a salary between £8006 and £9015 per annum fixed according to age, qualifications and experience. The post will be available for a fixed term of three years and will be superannuable.

Closing date: 31st August 1981.

For further information please write to or telephone Warrington (0925) 65000 Dr. P. J. Duke (Ext. 460). Applications should be sent together with curriculum vitae and the names and addresses of two referees, quoting reference number DL/765/N to:

DARESBURY LABORATORY

Science & Engineering Research Council Daresbury, Warrington WA4 4AD.

University of London
British Postgraduate Medical Federation
Cardiothoracic Institute
Cardiac Muscle Research Unit

Research Assistant Electron Microscopy/Cell Biology

Applications are invited for the above post to work with Dr N. J. Severs on membrane structure in cardiovascular muscle and endothelial cells. Freeze-fracture techniques are to be the principal tools in this project, and preference will be given to candidates with previous experience in electron microscopy. A keen interest in membrane structure and function is essential. The post is funded by the British Heart Foundation, and will be available for three years from October 1st 1981. Candidates should have (or expect to obtain) a first or upper second class honours degree. The successful applicant will have the opportunity to register for a higher degree.

The salary will be on the base point of the pre-doctoral research assistant scale, currently £5,285 + £967 London Allowance. The post is superannuable in the Universities' Superannuation Scheme.

Application forms from the Secretary's Office, Cardiothoracic Institute, 2 Beaumont Street, London W1N 2DX, to be returned not later than 24th July, 1981. (8952)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF HUMAN GENETICS

Applications are invited for the post of

POST DOCTORAL RESEARCH FELLOW

in the above Department to study immunological approaches to therapy in Cystic Fibrosis with particular regard to Phagocytic cell function. Previous experience of cell separation techniques and with human phagocytic cells would be an advantage. The post is available for three years from a date to be arranged.

The salary will be on the IA scale for Research Staff which starts at £6,070, according to age, qualifications and experience.

Further details from Dr J A Raeburn, University Department of Human Genetics, Western General Hospital EH4 2XU (Tel 031-332 2471 ext 177), to whom applications should be sent not later than 3rd August, 1981.

Please quote Reference no. 5030. (8973)A

UNIVERSITY OF CALIFORNIA AT LOS ANGELES FACULTY POSITION

The University of California at Los Angeles has an opening for a tenure (Associate or Full Professor) faculty position in the Department of Atmospheric Sciences. The applicant's research specialization should be in the field of atmospheric radiation, preferably with emphasis on applications to the dynamics of planetary atmospheres. The candidate should have an exceptional record of accomplished research and will be expected to develop a high-quality, independent research program at UCLA. Demonstrated experience in graduate and undergraduate teaching is desirable.

Applications will be accepted until March 1, 1982. The appointment can be effective as early as July 1, 1982. Interested inviduals should submit a letter of intent to: Professor Hans R. Pruppacher, Chairman, Dept of Atmospheric Sciences, University of California, Los Angeles, CA 90024. Tel: (213) 825-1954.

The University of California is an equal opportunity/affirmative action employer. (NW719)A

THE ROYAL SOCIETY OF CHEMISTRY

EDITORIAL STAFF

A Chemistry Graduate is required for editorial work on the Society's publications. A good degree or equivalent in chemistry is essential, and a proven ability to write in clear concise English will be an asset. Further particulars and application forms may be obtained from: Mrs. S. Sheldon, Assistant Personnel Officer, The Royal Society of Chemistry, 30 Russell Square, London WC1B 5DT. Telephone: 01-580 3482. Closing date — 17 July 1981.

(8984)A

WESTMEAD CENTRE SENIOR RESEARCH OFFICER —

PULMONARY PHYSIOLOGY (Advert No: H34)

Salary: A\$19,132 - A\$21,703

Qualification: PhD with experience in pulmonary physiology.

Duties: Full time research in lung and chest wall mechanics, gas mixing and ventilation distribution, working with Dr L A Engel (formerly at McGill University). The position is available immediately for a 3 year period. Westmead Centre is a new 925 bed teaching hospital of the University of Sydney with excellent facilities.

Hours of duty: 0830 - 1700.

Enquiries and official application forms: Dr L A Engel, Respiratory Medicine Unit, Westmead Centre. Telephone: (02) 6336797.

Applications with full curriculum vitae and names and addresses of 2 referees to be addressed to: The General Superintendent, The Westmead Centre, PO Box 264, Westmead, NSW 2145, Australia.

THE UNIVERSITY OF LEEDS

DEPARTMENT OF FORENSIC MEDICINE

Applications are invited for a post of postdoctoral

RESEARCH FELLOW

in the Department of Forensic Medicine for work on Histological localisation of drugs involving the use of fluorescence techniques, microscopical methods and possible immunological techniques. The appointment will be made for a fixed period of up to three years from 1981.

Applications should have a PhD in Pharmacology or Biochemistry and/ or relevant experience.

Salary on the IA Range for Re-search and Analogous Staff (\$6,070 £10,575) according to age, qualifications and experience.

Informal enquiries be made to Professor D J Gee, Department of Forensic Medicine (Telephone 0532-33144 Ext 5684).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 90/10/D. Closing date for applica-(8963)A tions 23 July 1981.

POSTDOCTORAL Research Associates to study the role of calmodulin in cell functions. Specific projects include (1) adenylate cyclase and phosphodiesterase, (2) prostaglandin metabolism and enzymology, (3) calmodulin-binding proteins, and (4) immunocytochemistry. Successful applicants may begin immediately. Send curriculum vitae and three letters of reference to Dr Wai Yiu Cheung, Department of Biochem-istry, St Jude Children's Research istry, St Jude Child.
Hospital, Memphis, Tennesse (NW724)A Tennessee

UNIVERSITY OF KEELE DEPARTMENT OF GEOLOGY DEPARTMENTAL **DEMONSTRATORSHIPS**

Applications invited for post of Demonstrator, available from 1 October 1981. Appointment for one year in first instance, conditionally renewable up to three years. Successful candidates expected to assist with teaching of both elementary and advanced laboratory courses in various aspects of Geology (including Geochemistry and Geo-physics). Some postgraduate expe-rience in research or in industry essential and knowledge of igneous and/or structural geology an advantage.

Initial salary £5,285 on the Other Relate 1B scale with membership of the University superannuation

Further details and application forms from Professor G Kelling, Department of Geology, The University, Keele, Staffs. ST5 5BG (Tel. No. 0782-621111). Application forms (in duplicate) should be returned to the Registrar, University of Keele, not later than 10 July 1981. (8942)A

Silicon Processing Development, Implementation and Control

IBM United Kingdom Laboratories Limited at Hursley, near Winchester, comprises the company's largest development facility outside the USA. To join the section providing pre-production fabrication support to the IC design groups, we seek an engineer with at least 3 years' experience in silicon IC processing and device physics.

This team, which reports directly to the Director of Advanced Technology, is responsible for developing and operating new process facilities in the Hursley Laboratory, and for obtaining all relevant information and assistance from our manufacturing plants and development laboratories in Europe and the USA.

The successful applicant will be required to visit these locations, and also direct the work of up to three engineers and technicians. A graduate of Electronics or Physics, the ideal man or woman will have practical experience of computer-controlled test systems and of test data reduction.

As a Company making a substantial contribution to the country's economy - over £600m in the last 10 years - IBM employs 15,000 men and women at over 40 locations throughout the UK Some 4,000 work at our two manufacturing plants and another 1,500 here at the Hursley

In addition to an attractive salary, a substantial employee benefits package is offered which includes a non-contributory pension scheme, free life assurance and BUPA membership.

Please telephone Mike Shute, Personnel Officer on Winchester (0962) 4433, Extension 6413 for an application form or write to him at: IBM United Kingdom Laboratories Limited, Hursley Park, Nr. Winchester, Hampshire SO21 2JN. Please quote reference: N/92282.

UNIVERSITY OF QUEENSLAND Australia

DEPARTMENT OF MATHEMATICS

LECTURER IN **NUMERICAL ANALYSIS**

Applicants should possess a PhD degree and a strong theoretical background in mathematics together with experience in research in a major area of numerical analysis. 14 August 1981.

LECTURER IN **BIOCHEMISTRY**

Applicants should have a PhD in Biochemistry and have a strong commitment to both teaching and research in Biochemistry. 31 July

TEMPORARY LECTURER IN ZOOLOGY

(1.1.82 - 31.12.82)

Primary responsibility Vertebrate Anatomy and Introductory Parasitology for first year Medical students; fisheries biology for level 3 Science students and some graduate supervision. Possible extension of appointment until 31.8.83. 31 August

Salary: \$A19,821 - \$A26,037 pa.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (8992)A

UNIVERSITY OF PENNSYLVANIA

PHARMACOLOGY DEPARTMENT

The Department of Pharmacology has openings for up to six

FACULTY MEMBERS

Emphasis will be on recruitment at the rank of Assistant Professor, but a limited number of tenured positions are also available. Applicants must have an advanced degree and at least two years of post doctoral research experience. Preference will be given to individuals with background in molecular pharmacology, neuro-pharmacology, or analytical phar-macology, but applications from outstanding candidates in any area relevant to pharmacology will be welcome. One position may relate to problems in ophthalmology. These positions will be available over a period of 18 months beginning in October of 1981. Each appoint will include the use of newly renovated, air conditioned laboratory space and reasonable start-up funds.

Applications from female and minority persons are especially encouraged.

Inquiries, which should include curriculum vitae, list of publications, reprints or preprints of selected papers and at least three letters of reference, should be addressed to: Faculty Search Committee, Department of Pharmacology, University of Pennsylvania, School of Medicine, Philadelphia, Pa. 19104. An equal opportunity/affirmative action employer. (NW715)A

UNIVERSITY OF HONG KONG LECTURESHIP IN **PHYSIOLOGY**

Applications are invited for a Lectureship in Physiology. The appointee will be required to participate in the teaching of physiology to dental and medical students. Applicants with higher degrees in Physiology or medical degrees will be given preference.

Applicants should have some research and teaching experience and a special interest in Cardiovascular Physiology.

Annual salary (superannuable) is: HK\$95,700 x 6,480 - 108,660 BAR $115,140 \times 6,420 - 160,080$ (£1 = HK\$10.80 approx.). Starting salary will depend on qualifications and experience. A medically-qualified appointee who has just completed his pre-registration year will be appointed as a Lecturer at the minimum point of the scale.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowance, leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts.), 36 Gordon-Square, London WC1H 0PF, or from the Appointments Unit, Secretary's Office, University of Hong Kong, Hong Kong.

The closing date for applications is 31 July 1981. (8969)A

Toxicologists

to evaluate data on Medical Aspects of Chemical Hazards

There are currently opportunities at two levels, to join the London-based Division which provides advice to Government Departments on all medical aspects of chemical contamination of the environment. A data bank is maintained on all subjects relevant to this work.

Up to £13,555

Work includes the evaluation of biological data in order to advise on possible health hazards associated with the following areas:-

Post I — Tobacco, tobacco substitutes and tobacco additives.

Post II — Food additives and contaminants.

Post II — Food additives and contaminants Candidates should normally have a first or second class honours degree in an appropriate subject plus a range of varied experience on work concerning chemical pollution and environmental protection. Experience in toxicological research and/or critical assessment of toxicological data is essential.

Appointment as Principal Scientific Officer £10,705 — £13,555 with starting salary according to qualifications and experience. *Ref:* S(B)677/2.

Up to £9,015

This post is concerned with the evaluation of

toxicological data relating to the exposure of man to chemicals in food. The successful candidate will join a multi-disciplinary team engaged on the preparation of monographs of toxicological data, background papers and briefing material for consideration by expert advisory committees in the UK and abroad. There will be opportunities to gain further practical experience in the Department's new toxicological laboratory at St Bartholomew's Hospital.

Candidates, normally aged under 30, should have a degree/HND/HNC in an appropriate discipline and at least 2 years post-qualification experience with a relevant biological/chemical background.

Appointment as Higher Scientific Officer £7,090 — £9,015 with starting salary according to qualifications and experience. *Ref:* SB/8/KE/2.

All salaries under review.

All successful candidates will be required to take the Diploma in Toxicology and will be given every encouragement in their studies, including day release.

In certain circumstances, assistance with removal expenses may be available.

For further details and an application form (to be returned by 24 July 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote appropriate reference.

NEW ZEALAND

PETROLEUM GEOPHYSICIST New Zealand Geological Survey

New Zealand is undergoing major expansion of its energy resource investigations including prospecting for hydrocarbons. The Department of Scientific and Industrial Research, the principal Government R & D Agency, and advisor to Government and industry in science and technology, has a vacancy in its Geological Survey for a seismic interpreter. The position, in the Petroleum and Basin Studies Section requires a person with a sound geological background primarily for regional analysis for the Basin Studies Programme.

Qualifications: A good 4 year bachelor's degree or higher, and at least 3 years petroleum exploration experience, are preferred.

Salary: A salary of up to NZ\$23,520 per annum is offered for this position, depending on qualifications and experience.

Further information, application forms etc may be obtained from the Chief Migration Officer, New Zealand High Commission, New Zealand House, Haymarket, London SW1Y 4TQ, quoting Imm 2/335/39.

Applications quoting Vacancy No. 2557 accompanied by a résumé should reach the above address by 30 September 1981. (8975)A

MEMORIAL UNIVERSITY OF NEWFOUNDLAND DEPARTMENT OF BIOCHEMISTRY PROSPECTIVE POSTDOCTORAL TRAINEES

graduate students and research fellows are encouraged to apply for research positions in the area of environmental and marine biochemistry, antifreeze porteins, membrane glycoproteins, intermediary metabolism, physical chemistry of lipids and proteins, experimental and community nutrition, microbiology, food sciences, food processing and food engineering. Grant-funded research in these areas is conducted in wellequipped laboratories by highly motivated research faculty. Salaries of postdoctoral and research fellows, other benefits and starting dates are negotiable. Fellowships of graduate students may be supplemented from grants and teaching assistantships.

Apply with vitae and two letters of recommendation to Dr S Mookerjea, Head, Department of Biochemistry, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X7, Canada. (8941)A

ASSISTANT RESEARCH SCIENTIST

AT UNIVERSITY OF CALIFORNIA SAN DIEGO

Research on role of central nervous system. Steroid hormone receptors in control of blood pressure. Two years of postdoctoral experience in steroid and/or neurotransmitter receptor work preferred. Salary \$22,500 plus, depending on experience. CV to Prof. D. D. Fanestil, University of California, San Diego, M-023, La Jolla, CA 92093.

An Equal Opportunity/Affirmative Action Employer. (NW722)A

TUFTS UNIVERSITY SCHOOLS OF MEDICINE

DEPARTMENT OF PHYSIOLOGY

Tufts University has instituted a search for

CHAIRPERSON

Department of Physiology. The department of physiology is expected to be a center of research and scholarly excellence, as well as providing leadership in physiology instruction for the School of Medicine, School of Dentistry, School of Veterinary Medicine, and the Sackler School of Graduate Medical Science.

Individuals interested in being considered for this position should direct thier letters to Dr Seymour Reichlin, Chairman, Physiology Search Committee, Box 275, New England Medical Center Hospital, 171 Harrison Avenue, Boston MA 021111. Tufts has an affirmative action program, and encourages applications from women and members of minority groups.

Babraham, Cambridge CB2 4AT

POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a post doctoral appointment financed for a period up to 3 years by the National Research Development Corporation in one of the following fields:i) Chemical carcimogemesis and cell transformation in vitro;

ii) Hybridoma production. Both areas will involve study of animal and/or human cells secreting hormones or antibodies.

Candidates should have a 1st or upper 2nd class honours degree and at least 2 years post-graduate experience in molecular biology and/or immunology and aquaintance with cell culture techniques.

Salary in Higher Scientific Officer scale (under review) £6,075 to £7,999 pa. Starting pay according to experience non contributory pension scheme.

This post can be discussed in more detail with Dr W Mason on Cambridge (0223) 832312. Application forms from the Secretary of the Institute quoting reference NRDC1. Closing date: 31.7.81. (8999)A

THE MEDICAL RESEARCH **COUNCIL OF NEW ZEALAND**

VIRUS RESEARCH UNIT Dundedin, New Zealand

DIRECTOR

Applications are invited from either medically or non-medically qualified virologists for the position of Director of the Council's Virus Research Unit, Department of Microbiology, University of Otago, Dundedin. The Unit has an establishment of five professional and six technical positions. As a result of an increase in establishment, two junior professional and two technical posts are currently vacant. Council would expect the Director to initiate a research programme of full international standard built around any medically significant viral system. While it is desirable for a portion of the research effort to be orientated towards clinically significant problems, the prime object of the unit is the pursuit of fundamental research in virology.

Salary would be not less than that of Associate Professor in the University. A particularly well qualified individual could be appointed at the level of full Professor.

Current salaries are: Associate Professor (Science)

NZ\$33,050 per annum. Associate Professor (Medical) NZ\$40,778 — \$45,987 per annum. Professor (Science) NZ\$35,564 — \$44,505 per annum.

Professor (Medical) NZ\$45,250 -\$50,464 per annum.
A 5% General Wage Order is

expected to apply.

Further particulars are available from the Registrar, University of Otago, Dunedin, New Zealand, or the Association of Commonwealth Universities (Appts.), 36 (Square, London WC1H 0PF. 36 Gordon

Applications close on 31 July, 1981, or as soon as possible (8970)A thereafter.

NATIONAL BLOOD TRANSFUSION SERVICE **Lancaster Centre**

Quernmore Road, Lancaster invites applications for the post of Senior Medical Laboratory Scientific Officer. Candidates should possess the Fellowship of the I.M.L.S. and preferably have the Advanced Certificate in Blood Group Serology or appropriate scientific degree with relevant experience.

The successful applicant will assume supervisory duties in connection with technical work carried out in various departments at the Centre.

Some evening work is envisaged and the appointee will be invited to participate in the emergency on call rota

Salary scale £6,129 to £8,097 per annum, increase pending. National Health Service conditions and superannuation scheme.

Applications, together with the names and addresses of two referees should be addressed to the Consultant in Charge to reach the Lancaster Centre by 14th August, 1981 (8988)A

UNIVERSITY OF PENNSYLVANIA

DEPARTMENT OF HUMAN GENETICS

THREE TENURE TRACK **POSITIONS**

to begin at the Assistant Professor level are available in the Department of Human Genetics. Candidates (MD or PhD) trained in modern molecular genetic techniques and with a record of research in genetics are urged to apply.

One position is to be filled by an MD researcher who would be qualified to hold a joint clinical appointment. Areas of interest in molecular approaches include: evolution, development, gene regulation, molecular cytogenetics, polymorphism and molecular mechanism of disease.

Send résumé to: Dr R Schmickel, Dept of Human Genetics, Room 195 Med Labs Bldg/G3, University of Pennsylvania, Philadelphia, PA 19104. An Equal Opportunity/ Affirmative Action Employer.

(NW726)A

UNIVERSITY OF ABERDEEN DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING

RESEARCH ASSISTANT

Applications are invited from Physicists with experience in medical physics required for a project funded by the Cancer Research Campaign to study the improved detection of early metastatic disease by combined use of radionuclide tomographic imaging and serum biochemical markers, working with Dr P P Dendy.

The appointment will be tenable until 30 September 1982 in the first instance, to commence as soon as

Salary on Range IB Scale £5,285 -£7,700 per annum, with appropriate

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by Friday 17 July 1981. (8945)A

UNIVERSITY OF NOTTINGHAM

CANCER RESEARCH CAMPAIGN LABORATORIES POST-DOCTORAL

CELLULAR IMMUNOLOGIST

Applications are invited for a postdoctoral post supported by the Cancer Research Campaign to join a group studying cellular immune responses to tumours. This includes the analysis of natural cell mediated immunity and its modulation by interferon and related substances.

The appointment will be initially for a period of twelve months. Salary will be in the range £6,070 to £10,575 per annum.

Applications in writing, enclosing a curriculum vitae including 2 referees, to the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD, not later than 31st July 1981. Ref No 789. (8998)A

RESEARCH SCIENTIST MARINE SEISMOLOGY

Salary: To \$39,889

Ref. No.: 81-NCRSO-EMR-10

Energy, Mines and Resources Canada Geological Survey of Canada (GSC)

Dartmouth, Nova Scotia

The Atlantic Geoscience Centre located at the Bedford Institute in Dartmouth has a vacancy for an experienced seismologist to lead the marine seismic programs of the Atlantic Geoscience Centre. The successful candidate will participate in and co-ordinate the GSC involvement in international, multi-institutional marine seismic reflection and refraction programs; will initiate, conduct and interpret the results from seismic programs of local, national or international scope. Programs are directed towards the investigation of the structure and origin of continental margins off Eastern Canada and the Arctic. This seismologist will be required to contribute original and creative research work.

Qualifications

Graduation with a Doctorate degree or a lesser degree with research experience and productivity equivalent to a Doctorate degree from a recognized university in one of the earth sciences (or a related field with considerable earth science experience) with previous seismological experience preferably in marine seismology and a demonstrated capacity for original geophysical research, its organization and coordination.

Knowledge of the English Language is essential.

Clearance No.: 111-077-001

Additional job information is available by writing to the address below:

Toute information relative à ce concours est disponible en français et peut être obtenue en écrivant à l'adresse suivante:

How to apply

Send your application form and/or résumé to: Joan Girling **National Capital Region Staffing Office Public Service Commission of Canada**

300 Laurier Avenue West Ottawa, Ontario K1A 0M7 (613) 593-5331

Closing date: July 31, 1981

(NW714)A

Please quote the applicable reference number at all times.

UNIVERSITY OF OXFORD UNIVERSITY LABORATORY OF PHYSIOLOGY

Departmental Demonstratorship

Salary: £5,285 - £8,105 (National Lectureship Scales)

The Department of Physiology invites applications for a Departmental Demonstratorship. The initial appointment will be for three years, with the possibility of renewal for a further three-year period. Departmental Demonstrators take part in all aspects of the teaching of physiology to medical and non-medical undergraduates, but are expected and encouraged to conduct their own research. Applications are invited from able candidates in any area of physiology or related disciplines.

Applications (3 copies) including the names of two academic referees should be sent by 30 September 1981 to: The Administrator, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT. (8947)A

Newcastle Area Health Authority (Teaching)
Royal Victoria Infirmary
Regional Genetics Advisory Service

SCIENTIFIC OFFICER BASIC GRADE

Graduate required immediately for work in active cytogenetics service laboratory involved in all aspects of diagnostic cytogenetics including leukocyte culture, amniotic fluid cell culture, fetal cultures and bone marrow analysis. Previous experience preferable but not essential. For further information please contact Professor D. F. Roberts, telephone Newcastle (0632) 25131, Extension 658.

Salary on Whitely Council PTA Scales: Probationary 1st or 2nd Class Honours Degrees: £5,346 \times 5 increments to £6,363 pa. Other Degrees: £4,839 \times 7 increments to £6,363 pa. Post-Probationary Scale: £5,553 \times 7 increments to £7,110 pa.

Applications giving full personal details, together with the names and addresses of two referees should be sent to the Senior Administrative Assistant (Personnel), Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, quoting Ref. No. 81/41. Closing date: 17 July 1981.

University of Kent at Canterbury Space Sciences Laboratory GIOTTO COMET HALLEY MISSION

A new team sponsored by the European Space Agency and financed by the SERC is being formed under the direction of Dr J. A. M. McDonnel to develop a Principal Investigator experiment for the interception of Comet Halley 1986. The team will design and co-ordinate the development of a sensor cometary dust impact system in co-operation with the Rutherford and Appleton Laboratories (RAL) and 11 co-investigators in Europe and the USA. Applications are invited for the following vacancies.

PROJECT MANAGER to be responsible to the Principal Investigator for the design, development, test and integration work to be carried out at the University in co-operation with RAL and ESA, Holland. Applicants should have experience in the aerospace and electronics fields. Initial appointment is for 3 years with probable extension until 1986. The salary will be between £8,515 and £12,305 within the IA/II range for research and analogous staff.

ELECTRONIC DESIGN ENGINEER (Graduate Research Associate) to design and develop high reliability, low-power circuitry. Experience in electronic design engineering would be an advantage. Salary range £5,285 — £6,880 on the Grade IB scale for other related staff.

ELECTRONICS TECHNICIAN GRADE 3 to develop and fabricate prototype flight circuits and to test manufactured flight systems. Salary range £4,672 — £5,066 on the Grade 3 scale.

Successful applicants would be expected to travel within Europe. The appointments will be made as early as possible and applications giving details of qualifications and experience and the names of two referees should be submitted to the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH, from whom further particulars may be obtained. Please indicate the post applied for and quote reference A18/81. Closing date 31 July 1981.

UNIVERSITY OF PAPUA NEW GUINEA (Port Moresby)

Applications are invited for the post of PROFESSOR OF CHEMISTRY

A major responsibility of the Department is in undergraduate teaching. This includes relatively elementary service teaching, but also more advanced courses for science and chemistry students. Applicants should have a strong interest in the problems of teaching chemistry in Papua New Guinea at all levels covered in the University. Department is committed to the training of National Academics and a significant contribution will be expected in this area of avanced training. Present research in the Department includes: chemical education; chemistry of natural products; general environmental and analytical chemistry; heavy metal contamination of the environment; kinetics and reaction mechanisms of co-ordination complexes; marine chemistry: nutrient composition of the winged bean; phytochemistry of medicinal plants; X-ray crystallography. The interests of the Professor need not be confined to these areas, but should be in the general area of application of chemistry to Papua New Guinea and its environment. Applicants should have wide research capabilities and extensive research experience in at least one appropriate area. Previous experience of teaching and research in a developing country in a tropical environment will be considered an advantage.

Salary: K 20,995 pa. Three-year contract; gratuity; support for approved research; rent-free accommodation; family passages; baggage allowance; leave fares after 18 months service; education subsidies; salary continuation scheme to cover extended illness or disability. Applicants who wish to arrange secondment from their home institutions will be welcomed.

Detailed applications (2 copies), including a curriculum vitae, a recent small photograph, a written statement outlining their views on the role of chemistry in a developing tropical country and naming 3 referees, should be sent to the Assistant Secretary (Staffing), University of Papua New Guinea, Box 4820, University PO, Papua New Guinea to arrive no later than 3 August 1981. Applicants resident in UK should also send I copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London WIP ODT. Further details are available from either address.

(8949)A

THE AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF CHEMISTRY

RESEARCH FELLOWS

Applications are invited for appointment as postdoctoral Research Fellow in the Research School of Chemistry. Appointments will be for two years in the first instance Current major research interests in the School are:

Organic Chemistry (Professor A I J Beckwith, Professor L N Mander Mr R W Rickards, Dr J K Macleod Dr L Radom): including free radica reactions; mechanistics and synthetic organic chemistry; organic chemistry biologically active compounds ICR and mass spectrometry; ESR spectroscopy; theoretical organic chemistry. Inorganic Chemistry (Professor B G Hyde, Professor A M Sargeson, Dr M A Bennett, Dr G E chemistry. Robertson, Dr S B Wild): including solid state inorganic chemistry synthesis, structure and reaction mechanisms of transition metal complexes: biomimetic chemistry organo-transition metal chemistry X-ray crystallography; resolution and reactions of chiral arsines and phosphines. Physical and Theoretica. Chemistry (Professor D P Craig, Dr J Ferguson, Dr R Bramley, Dr T R Welberry): including molecular and crystal theory; spectroscopy and photochemistry; photophysics and EPR; X-ray diffraction and theoretical studies of disordered materials Analytical Chemistry: Miss B J

Appointments will be made primarily within these research groups, but proposals for independent research will also be considered Further particulars on the appointments may be obtained on request.

Salary range \$A19,821 — \$A25,871 per annum. Current exchange rates \$A1 = 58p = \$US1.11. Reasonable travel expenses and assistance with housing for appointees from outside Canberra. Superannuation benefits are available. There is no application form.

Applicants should supply to the undersigned by 31 August 1981 a curriculum vitae, list of publications and statement of research interests together with two passport-sizec photographs, the names and addresses of three academic referees and the probable date on which the post doctoral Research Fellowship, if awarded, could be taken up. G E Dicker, Registrar, PO Box 4, ACT 2600, Australia.

Further particulars can also be obtained from the Association of Commonwealth Universitie: (Appts.), 36 Gordon Square, Londor WC1H0PF. (8938)A

THE UNIVERSITY OF ALBERTA

DEPARTMENT OF IMMUNOLOGY

has two vacancies for

POST-DOCTORAL FELLOWS

to work on the following research projects: a) cell-mediated and humoura immune responses to virus-transformed tumours, involving analysis of tumou rejection in vivo in a murine model; b) characteristics of cytotoxic T Cell responses to minor H antigens.

Send resume and names of referees to Dr L M Pilarski, Department of Immunology, University of Alberta, 845E Medical Sciences Building, Edmonton Alberta, Canada T6G 2H7. The University of Alberta is an equal opportunit employer. (NW720)A

UNIVERSITY OF SOUTHHAMPTON RESEARCH TECHNICIAN IN ORGANIC CHEMISTRY

A technician is required by the Department of Chemistry for support in the Research Laboratories. The work will involve synthetic chemistry and supervision of gc, hplc and spectroscopic equipment, leading to a wide range of experience.

Applicants should have an appropriate science qualification (at least ONC/TEC or equivalent) and relevant background experience.

The appointment will be made on grade 4 salary scale £5,284 — £6,078 or grade 5 £5,695 — £6,650 per annum, depending upon age, qualifications and experience.

Applications (two copies) giving date of birth, details of qualifications and experience together with the names and addresses of two referees should be sent to Mr C N Saull, Staffing Dept., The University, Southampton SO9 5NH as soon as possible quoting reference no. 462/T. (8989)A

UNIVERSITY of Arizona, faculty position at any academic rank. The Department seeks applications from candidates with expertise in basic science and ability to apply this expertise to problems in food science and food production. Basic science areas such as ultrastructural analysis, recombinant DNA, cell culture, or physical chemistry are of particular interest, but all areas will be considered. The successful candidate will be expected to develop a vigorous, independent research program in their speciality area. 12-month position, 90% research, 10% instruction. Applications including the names of three referees should be sent to: Darrel E Goll, Nutrition and Food Science, University of Arizona, Tucson, Arizona 85721 USA. Equal Opportunity/Affirmative Action Employer. (NW725)A

UNIVERSITY OF TORONTO DEPARTMENT OF MEDICAL GENETICS ASSISTANT PROFESSOR Tenure Stream

Applications are invited from MD's or PhD's with postdoctoral research training and a strong background in the molecular genetics of higher organisms or the application of molecular genetics to medical or related problems.

Appointee would be expected to lead an independent research program in area of expertise and participate in the teaching of molecular and cell biology. Salary is commensurate with experience.

Applications, giving names and addresses of three referees, should be sent to Dr Andrew Becker, Department of Medical Genetics, University of Toronto, Toronto, Canada M5S 1A8 before July 31, 1981. (NW716)A

QUEEN ELIZABETH COLLEGE Kensington (University of London) LIBRARIAN

Applications are invited from graduates with appropriate qualifications for the post of Librarian which becomes vacant on 1 October 1981. A scientific background is most desirable as the College in its teaching and research spans the physical and biological sciences. The Librarian will be responsible for completing the on-line computerised circulation system and for applying other up-to-date information technology.

The salary will be within the scale £12,305 — £15,410 pa, plus London allowance of £967 pa.

Application form and further particulars from the College Secretary, (N) Queen Elizabeth College, Campden Hill Road, Kensington, London W8 7AH. Tel: 01-937 5411 ext. 209. Closing date: 24 July 1981. (8950)A

INSTITUTE OF CANCER Research: A post-doctoral post is available for a period of three years in the Division of Cell and Molecular Biology, Chester Beatty Research Institute, Fulham Road, SW3, (Head, Dr R A Weiss). The project involves the study of the genetics of neoplastic transformation using cellular and molecular genetic techniques. Experience in somatic cell genetics, cell biology or mole-cular genetics would be advantageous although not essential. Starting salary in range £6,070 to £6,880 pa plus London Allowance of £967 pa. Further information may be obtained from Dr C. J Marshall, Tel: 01-352 8133, ext 262. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 300/G/5. (8997)A

THE UNIVERSITY OF ALBERTA

DEPARTMENT OF IMMUNOLOGY requires a

PROFESSIONAL RESEARCH ASSISTANT

to conduct a research project which involves analysis of the SV40 — TSTA and the immune response to SV40 — induced tumours. Applicants should possess a PhD with at least two years post-doctoral experience with expertise in the area of the biochemistry of cell surface proteins with emphasis on the cross-linking of proteins via bifunctional reagents. Salary \$20,000 — \$22,000 depending on experience.

Résumés should be sent to Dr L M Pilarski, Department of Immunology, University of Alberta, 845E Medical Sciences Building, Edmonton, Alberta, Canada T6G 2H7. The University of Alberta is an equal opportunity employer. (NW721)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

John Curtin School of Medical Research Department of Human Biology FFI LOW

The successful applicant will be required to take charge of the Department's laboratory on metabolic disorders and biochemical genetics. Demonstrated ability to carry out original investigations and supervise research in these fields will be essential and experience with the study of inherited haematological disorders will be an advantage.

Closing date: 31 October 1981.

Research School of Physical Sciences RESEARCH FELLOW IN SOLID STATE PHYSICS

The Department of Solid State Physics has two main fields of research — spectroscopy of non-metallic solids and the physics of crystalline and amorphous metals. It has two lasers (c.w. and pulsed) with associated dye lasers and is well equipped for studies in all aspects of solid state spectroscopy (EPR, Mossbauer, ultraviolet, visible and infrared) and in cryogenics and thermal properties of condensed matter. There are excellent facilities for materials preparation and supporting mechanical and electrical workshops.

Appointment will be from early 1982. Applications are welcome from those able to take leave from their own institutions. Closing date: 1 October 1981.

RESEARCH FELLOW IN THEORETICAL PHYSICS

The Department's main current interests are in theoretical aspects of nuclear physics, elementary particles and field theory, statistical mechanics, transport processes, solid state physics, and plasmas. It wishes now to make a non-tenured appointment in theoretical nuclear physics. Appointment will be from 1982. Applications are welcome from those able to take leave from their own institutions.

Closing date: 1 October 1981.

Term of appointment for Fellow will be for 5 years in the first instance with the possibility of reappointment after review to retiring age; for Research Fellow 3 years with the possibility of extension to 5 years. Salary on appointment will be in accordance with qualifications and experience within the ranges: Fellow \$A23,104 — \$A30,952 pa; Research Fellow \$A19,821 — \$A25,871 pa. Current exchange rate: \$A1=0.58np=\$US1.11.

Reasonable travel expenses are paid and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits are available for applicants eligible to contribute. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Registrar PO Box 4, Canberra ACT 2600, Australia, or from the Association of Commonwealth Universities (Appts.) 36 Gordon Square, London WC1H 0PF, before submitting applications. (8939)A

FRENCH PHARMACEUTICAL GROUP SANOFI

Cellular Pharmacology Research Opportunities

Applications are invited from CNRS or INSERM Scientists, or other French or Foreign Research Organizations, State Doctor or PhD, for creation of a stable team of Research in CELLULAR PHARMACOLOGY SANOFI RESEARCH.

This team will be settled in Toulouse and will work in close relations with CNRS Laboratory of Basic Pharmacology and Toxicology in Toulouse.

Salary at least at the level of Chargé 5 of CNRS dependent on qualifications, experience and scientific quality of publications.

Applications with curriculum vitae to: Staff Department, Sanofi Recherche, 195 route d'Espagne, F 31036, Toulouse.

(W373)A

Materials Science Technician

£5,751 — £7,134 p.a. inc.

An interesting opportunity at the Polytechnic's Enfield location, providing a full range of services for the Materials Science Laboratories. Responsibilities would include day-to-day management, preparation and presentation of materials for microscopic examination, and the identification, labelling and cataloging of new materials.

A good HNC or equivalent qualification in physics or materials science is expected, although at least five years industrial experience in one of those fields may be acceptable.

Write quoting ref: D315D for further details and an application form, posting first-class to: Personnel Office, Middlesex Polytechnic, 114 Chase Side, London N145PN. Closing date 13 July. (8987)A

Middlesex Polytechnic

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHYSICS RESEARCH SCIENTISTS

A three-year postdoctoral research position is available for work on a joint programme with British Petroleum under the direction of Dr A Howie, FRS for the application of high resolution scanning transmission electron microscopy to catalysis problems. Salary £6,475 — £7,290 pa.

Applications from physicists, chemists and materials scientists, preferably having some experience of electron microscopy, should be sent by 31 July 1981 to the Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 OHE, from whom further information can be obtained. (8960)A

UNIVERSITY OF READING

European Science Foundation — Additional Activity in Taxonomy Applications are invited for the following staff to participate in the establishment of a EUROPEAN TAXONOMIC SYSTEMATIC AND BIOSYSTEMATIC DOCUMENTATION SYSTEM project under the auspices of the European Science Foundation:

1. INFORMATION SCIENTIST to play a major role in devising a

computerised information system for plant taxonomic and related data on a European basis. The successful candidate will have a PhD and substantial experience in information science/systems design and with

an interest in plant systematics. Starting salary up to £12,860 p.a.

2. PLANT TAXONOMIST to work closely with the Information Scientist and be responsible for collecting and assessing data, both published and unpublished, on the taxonomy, systematics and biosystematics of European plants. The successful candidate will have a PhD and experience in plant systematics, with an interest in modern methods of data handling. Starting salary up to £8,515 p.a.

Both appointments are for up to three years in the first instance and are superannuated under USS. They will be based in the Department of

Botany, Plant Science Laboratories. Apply, quoting Ref. R.11A, for application form and further details to Personnel Officer, University of Reading, Whiteknights, Reading RG6 2AH. Application forms to be returned by 15 August 1981.

ASSOCIATESHIPS

UNIVERSITY OF ADELAIDE

Invites applications for three

RESEARCH ASSOCIATESHIPS (X3503, X3504 & X3505)

which it proposes to award in 1981. Each award may be held in any department of the University.

Applicants should have gained their postgraduate qualifications elsewhere than at The University of Adelaide. In those disciplines where a PhD is a recognised indication of research ability such a degree will be required. In other areas, appropriate evidence of research ability will be required.

An Associateship will be tenable for two years and will not be renewable; no age limit governing eligibility has been specified but normally a 10 year limit since the award of the most recent higher degree qualification will apply.

Travel Provision: The University will provide, for a person taking up appointment from outside South Australia, an economy class air fare to Adelaide by the shortest practicable route. There is no provision for transfer of personal effects.

Salary Scale: A17,083 - 497(1) - 500(1) - 499(1) - 493(1) - 498(1)\$A19,570. There is no provision for superannuation.

Applications in duplicate must be made on the prescribed form. Forms and a leaflet outlining conditions of appointment may be obtained from the Secretary, Research Sub-Committee, Registrar's Office, The University of Adelaide. Applications must be lodged with the Registrar of the University, GPO Box 498, Adelaide, South Australia, 5001, not later than 1 August, 1981. (8940)O

CONFERENCES and COURSES

CHARLES DARWIN CENTENARY CONFERENCE 27 June — 2 July 1982

Darwin College Cambridge is promoting this Conference on the centenary of Darwin's death to survey the present state and prospects of evolutionary theory. The Conference will be primarily scientific rather than historical, but not intended only for specialists. The Conference will be strictly limited in size: early application is advised.

Speakers include -

Introduction: S. Brenner

Evolutionary History: E. Mayr, M.J.S. Hodge, D.L. Hull, G.E. Allen

Molecular & Cellular Evolution: L.E. Orgel, F. Jacob, D. Phillips M. Eigen, W.F. Bodmer, C.R. Woese, P.H. Clarke, A. Wilson

Evolution of Whole Organisms: R.C. Lewontin, E. Nevo. J.L. Harper, S.J. Gould, A. Hallam, G. Isaac, F.J. Ayala Evolution of Social Behaviour: R.W. Burkhardt, J. Maynard Smith, T.H. Clutton-Brock, P.P.G. Bateson, R. Dawkins, E.O. Wilson, B.A.O. Williams

Registration Fee £40: full board and lodging about £30 a day. Details and application forms from Hon. Secretary, Darwin Centenary Conference, Darwin College, Cambridge CB39EU, U.K. (8996) C

BIRKBECK COLLEGE (University of London)

DEPARTMENT OF ZOOLOGY

MSc IN ENTOMOLOGY

This two-year part-time evening course is designed primarily for entomologists but also allows teachers and others to extend their training in a scientific discipline and to become conversant with the tools of the current research. Topics covered include: sensory and neuromuscular physiology, respiratory physiology, osmotic and ionic regulation, insect genetics, taxonomy and economic entomology.

For further details contact the Departmental Secretary, Department of Zoology, Birkbeck College, Malet Street, London WC1E 7HX

(8966)C

BIRKBECK COLLEGE (University of London)

DEPARTMENT OF ZOOLOGY

MSc IN COMPARATIVE **PHYSIOLOGY**

A two-year part-time evening course suitable for zoology graduates wishing to specialise in the comparative aspects of the adaptations of animals to their environment. Topics covered include: osmotic and ionic regulations; respiratory and circulatory physiology; endocrinology; neurophysiology. Students are introduced to a wide range of modern physiological techniques.

For further details contact the Departmental Secretary, Department of Zoology, Birkbeck College, Malet Street, London WCIE 7HX.

(8967)C

Kingston Polytechnic

MSc in EARTH SCIENCE AND THE ENVIRONMENT

The third intake for the two year part-time course will be in January 1982.

Send for further details to the Secretary, School of Geology, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366.

Applications should be submitted by 20th July 1981.

(8981)C

STUDENTSHIPS

LIVERPOOL POLYTECHNIC DEPARTMENT OF BIOLOGY RESEARCH STUDENTSHIPS

Applications are invited for Post Graduate Research Studentship to work on "Thallium Uptake by Plants".

Applicants should have an appropriate first degree with CNAA.

Applications in the first instance to Dr N. W. Lepp, Department of Biology, Liverpool Polytechnic,

Byrom Street, Liverpool L3 3AF.

Closing date two weeks after the appearance of this advertisement.

(8957)F

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

RESEARCH STUDENTSHIP

Applications are invited from individuals holding, or expecting to obtain, a good honours degree in Physiology or Pharmacology for a Research studentship tenable in the Department of Physiology, St. George's Hospital Medical School.

The successful applicant will work on a research project concerning the effects of alcohol on the nervous system of animals. Further details are available from Dr T W Stone, Department of Physiology, St George's Hospital Medical School, London SW17 ORE (Tel: 01-672 1255 ext 4657), to whom applications should be sent along with CV and names of two referees.

(8972)F

CHELSEA COLLEGE UNIVERSITY OF LONDON SRC CASE STUDENTSHIP

Applications are invited from andidates with a first or upper second class honours degree or equivalent qualification for a three year CASE Studentship on the Pharmacology of Enkephalinase

The research will be supervised by Dr S L Hart in collaboration with Dr I W Smith at the Wellcome Labora-

Applications, including curiculum vitae and names of two eferees should be sent as soon as possible to the Secretary, Pharnacology Department, Chelsea College, Manresa Road, London College, N SW3 3TW.

ARC UNIT OF NITROGEN FIXATION University of Sussex and Open University SERC CASE **STUDENTSHIP**

students with an interest in Bio-Organic Coordination Chemistry iolding, or expecting, a first or upper econd class honours degree this ummer, are invited to apply for the ibove studentship.

It concerns the application of 15N imr spectroscopy and other echniques to chemical systems elevant to biological nitrogen ixation, most experimental work to be carried out at the UNF.

The joint supervisors are Dr J Mason (Open University) and Dr R L Richards (Unit of Nitrogen Fixation, Jniversity of Sussex, Brighton BN1 IRQ) to whom applications, together vith the names of two referees should e sent as soon as possible. (8980)F

UNIVERSITY OF SUSSEX

SCHOOL OF **BIOLOGICAL SCIENCES** Falmer, Brighton BN1 9QG

SRC CASE AWARD

'Protein Metabolism in Animal Tissues During Pregnancy and Lactation'

A studentship is offered in collaboration between Dr V M Pain at the above address and Dr R Vernon at the Hannah Research Institute, Ayr, Scotland.

Applicants, or those seeking further details should contact Dr Pain (0273 606755 Ext 53) or Dr Vernon (0292 76013 Ext 227) as soon as possible. (8953)F

UNIVERSITY OF NOTTINGHAM

SCHOOL OF AGRICULTURE (DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES) CASE STUDENTSHIP

Applications are invited from candidates holding a First or Upper Second Class Honours degree for a 3-year SRC CASE studentship to work on the development of forage

The research will be supervised by Professor W J Whittington in collaboration with Dr J T Walker of Germplasm Resource Management Limited, Loughborough.

Applications, including curriculum vitae and names of two referees should be sent as soon as possible to Professor W J Whittington, University Nottingham, School of Agriculture, Sutton Bonington, Loughborough LE125RD. (8976)F

UNIVERSITY OF **BIRMINGHAM NEUROCOMMUNICATIONS** MEDICAL SCHOOL CASE STUDENTSHIP

Applicants with a good honours degree (I or II (i)) in Biochemistry/ Pharmacology are invited to apply for a CASE studentship for research on 'Taurine and central nervous system inhibitory processes'

Curriculum Vitae with the names of two referees to Dr W E Davies, Nuerocommunications, Medical School, University of Birmingham, Edgbaston, Birmingham B15 2TJ.

UNIVERSITY OF DURHAM DEPARTMENT

OF BOTANY Applications are invited for SERC CASE STUDENTSHIPS

as follows:

1. In collaboration with the Scottish Horticultural Research Institute to investigate the physiology of high pod setting new genotypes of the Vicia faba. (Supervisor Professor Boulter).

2. In collaboration with ICI Pharmaceutical Division to characterise biochemically the mechanisms of peptide transport in Candida albicans. (Supervisor Dr J

Candidates should have or expect to obtain a First or Upper Second Class Honours degree or equivalent qualifications.

Applications, naming two referees, should be sent to Professor D Boulter, Department of Botany, Science Laboratories, South Road, (8995)F Durham DH13LE.

BEDFORD COLLEGE (University of London)

DEPARTMENT OF ZOOLOGY

Applications are invited from candidates holding or expecting to graduate with a First or Upper Second Class Honours degree in Zoology or an appropriate related discipline for an

SRC CASE STUDENTSHIP

The award is available for research on "Geographic variation in Callosobruchus maculatus", a pest of leguminous seeds both on the plant and primarily in store, in collaboration with the Tropical Products Institute, Slough. The project will involve a bionomic study of distinct strains of the beetle from various tropical origins, with a view to identifying differences of potential importance in control of the pest in field situations.

Applications including a full curriculum vitae and the names of two referees should be sent as soon as possible to Dr P F Credland, Department of Zoology, Bedford College, Regent's Park, London NW14NS (01-486 4400), from whom further information may be obtained. (8968)F

PLYMOUTH POLYTECHNIC

FISH BIOLOGY **RESEARCH IN DEVON**

- 1) A NERC funded PhD studentship is available to suitably qualified candidates to work with Dr M. J. Manning and Dr J. E. Harris on developmental aspects of immunity and tolerance in fish.
- 2) A NERC funded Research Assistantship with the opportunity to register for a higher degree is available to work with Dr M. J. Manning on the rationale of immunising young fish against disease.
- 3) Plymouth Polytechnic offers a one-year MSc Degree by course-work and research in Applied Fish Biology with NERC-funded studentships for some selected candidates.
- 4) Plymouth Polytechnic also offers PhD (3 year) or MPhil (2 year) postgraduate research programmes in areas which include Parasitology, Immunology, Microbiology, Cell Biology and Genetics.

For further details please write

Dr M. J. Manning, Dr J. E. Harris or Dr R.A. Matthews, Department of Biological Sciences, Plymouth Poly-technic, Drake Circus, Plymouth PL48AA.

Details of other research opportunities in the Department are obtainable from Dr L. A. F. Heath, Head of Department of Biolog-(8944)F ical Sciences.

BIRKBECK COLLEGE

(University of London) DEPARTMENT OF ZOOLOGY Applications are invited for a three year

SRC CASE

RESEARCH STUDENTSHIP

to study neurophysiological and behavioural aspects of food selection by larvae of Spodoptera species (Lepidoptera) in collaboration with the Centre for Overseas Pest Research (Dr R F Chapman).

Applicants should have, or expect to obtain this summer, a first or upper second class honours degree in a biological discipline.

Applications, with curriculum vitae and names of two academic referees should be sent, as soon as possible, to Dr W M Blaney, Department of Zoology, Birkbeck College, Malet Street, London WC1E 7HX. (8965)F

THE UNIVERSITY OF WOLLONGONG New South Wales

DELHI PETROLEUM POSTGRADUATE AWARD IN GEOLOGY

Applications are invited from graduates with good honours degrees or equivalent in geology for a postgraduate award in the Department of Geology.

The Award is for research in the area of source rock and maturation studies in the Cooper and Eromanga Basins.

The award is available for full-time candidates undertaking research leading to the degree of Doctor of Philosophy and may be held for a maximum of 3 years subject to satisfactory performance, work and conduct. An award holder receives an annual stipend of A\$7,500 pa.

Further information is available from Professor A. C. Cook, Department of Geology.

Applications, giving the names and addresses of two referees, should be forwarded to the University Secretary, The University of Wollongong, PO Box 1144, Wollongong, 2500, NSW, Australia, no later thay July 31st, 1981. (8955)N

FELLOWSHIPS

UNIVERSITY OF MANCHESTER

DEPARTMENT OF BOTANY
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications invited for postdoctoral fellowship, tenable for maximum of three years, to work on factors controlling sporocarp development in the aquatic fern Azolla and other aspects of its biology. The fellowship is supported by the Overseas Development Administration and the International Rice Research Institute (IRRI), Manila, Philippines, and the Fellow will spend a few months of each year at IRRI.

Experience of electron microscopy (SEM and TEM) an advantage. Initial salary £6,880 to £7,700 pa.

Applications to Professor E G Cutter, Department of Botany, The University, Manchester M13 9PL, by 20th July, 1981. (8974)E

EMBO

European Molecular Biology Organisation LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1981 AWARDS

Next deadline: August 15, 1981

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but subject to review of progress by the selection committee, they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is August 15, 1981. Successful candidates will be notifed of their awards immediately after the meeting of the selection committee which is on October 23, 1981.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.

(W370)E

Department of Haematology

POST DOCTORAL FELLOWSHIP

Applications are invited for the above post in the Department of Haematology, Trinity College, Dublin

The successful candidate will work in the field of bone marrow culture and marrow transplantation. Previous experience in tissue culture is desirable, not essential.

Applicants should submit a full curriculum vitae, together with the names of two referees, to:

Dr. S. R. McCann, Central Pathology Laboratory, St. James's Hospital, Dublin 8. Tel: Dublin 782088.

(8986)E

POSTDOCTORAL FELLOWSHIPS available starting 1 July 1981. Experience in protein purification and/or RNA-DNA hybridization analysis preferred. (i) To study estrogen receptor mediated events related to gene transcription and (ii) to study the mechanism of alterations in gene expression related to prostate neoplasia. Send curriculum vitae, graduate transcripts, and three letters of recommendation to: Roy G. Smith, PhD, The University of Texas Medical School at Houston, 6431 Fannin, Suite 6018, Houston, Texas 77030. An Equal Opportunity Employer. (NW717)E

RESEARCH IMMUNOLOGIST BRITISH HEART FOUNDATION SENIOR FELLOWSHIP

Applications are invited for the post of Immunologist attached to the Papworth Heart Transplant Research Unit which is funded by the British Heart Foundation. The principal research activities will be directed towards studying the effects of presently used anti-thymocyte globulins and other immunosuppressive agents, and on the potential use of monoclonal equivalents.

The Fellow will have access to clinical material at Papworth Hospital but will be based in the Immunology Division of the Department of Pathology at Adenbrooke's Hospital, Cambridge. The appointment will be for 3 years in the first place. Salary will be according to age and experience on the University Lecturer Scale, or for medically qualified candidates the salary will be equivalent to that of a Clinical Lecturer.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Mr P Wilburn, Superintendent, Department of Pathology, Tennis Court Rd, Cambridge CB2 IQP. (8959)E

UNIVERSITY OF WARWICK POSTDOCTORAL FELLOWSHIP IN MASS SPECTROMETRY

To work in the Department of Chemistry and Molecular Sciences with Professor K R Jennings on the mass spectrometry of explosives and related compounds. The project involves the study of the negative chemical ionisation spectra of nitrocompounds under a variety of experimental conditions. The appointment will be for one year in the first instance. Salary up to £7,700 in the Research Range IA scale: £6,070 — £10,575 pa, depending on age and experience. Informal enquiries to Professor Jennings (Tel: 0203-24011 ext. 2232).

Applications should include a full curriculum vitae and the names of two referees to be sent to the Academic Registrar, University of Warwick, Coventry CV4 7AL as soon as possible. Please quote Ref. No: 46/A/81/O. (8985)E

POSTDOCTORAL Fellowship: To study hormonal regulation of vitamin D metabolism in mammals. Theoretical and/or practical experience required. Contact: Dr E M Spencer, Children's Hospital of San Francisco, 3700 California Street, San Francisco, Calif. 94118. Equal Opportunity Employer, M/F/H. (NW723)E

ASSOCIATESHIPS

UNIVERSITY OF EDINBURGH Department of Physics

RESEARCH ASSOCIATESHIP IN EXPERIMENTAL HIGH-ENERGY PHYSICS

Applications are invited for a Research Associateship (funded by SERC) within the high-energy physics group, which is engaged in hadron experiments at the CERN accelerators. Applicants should normally have three years' postgraduate research experience. The appointment will be made at an appropriate point on the 1A scale for research staff (currently starting point in the range £6,070 — £6,880 per annum).

Applications, with the names and addresses of two referees, should be sent, as soon as possible, to Dr D. J. Candlin, Department of Physics, James Clerk Maxwell Building, The King's Buildings, Mayfield Rd, Edinburgh EH9 3JZ, from whom further details may be obtained. Please quote reference No. 5028. (8954)O

The New England Journal of Medicine presents to its readers original articles of clinical-scientific material and interpretive reviews in the major disciplines of medicine. In this highly competitive field less than 10% of the manuscripts submitted are accepted for publication because of the rigid editorial policy that articles must reveal something new or be an extension of existing knowledge.

Every week, more than 200,000 subscribers keep up to date with the world of medicine through The New England Journal of Medicine. To join them, just fill in and mail the coupon today.

For photomicrography or cinemicrography, it pays to match Olympus microscopes with something equally outstanding: The Model PM-10AD. The PM-10AD faithfully records the high image resolution, definition and clarity of Olympus microscopes. Ancit does so with the convenience of fully automatic exposure.

The time and effort you save are remarkable. Thanks to a built-in microcomputer and a Silicon Blue Cell (SBC that relays information to it quickly an accurately, you need no longer worry about complicated adjustments. The automatic exposure range is ex-

tremely wide, from 1/5000 of a second to 2 hours. The microcomputer automatically corrects the reciprocity failure characteristics of the film you are using and operates continuously to yield perfect exposures.

The PM-10AD allows automatic and manual operation. In either mode, it can be used not only for conventiona purposes but also for multiple exposures of double-stained fluorescence specimens and panorama photography, in which case uniform density is assured.

Other features:

- •Clear digital displays include estimated and actual exposure times, time remaining to complete exposure and recall of the previous exposure time.
- •Unique vibration-free electromagnetic shutter. The contact-free design provides a shutter life of at least 100,000 operations with absolutely no adverse effects on image quality.
- •Optional PM-CTR color temperature meter module for simple checking and adjustment of color temperature.

A TRIUMPH OF INSPIRED SIMPLICITY. PM-10AD Photomicrography and Cinemicrography System

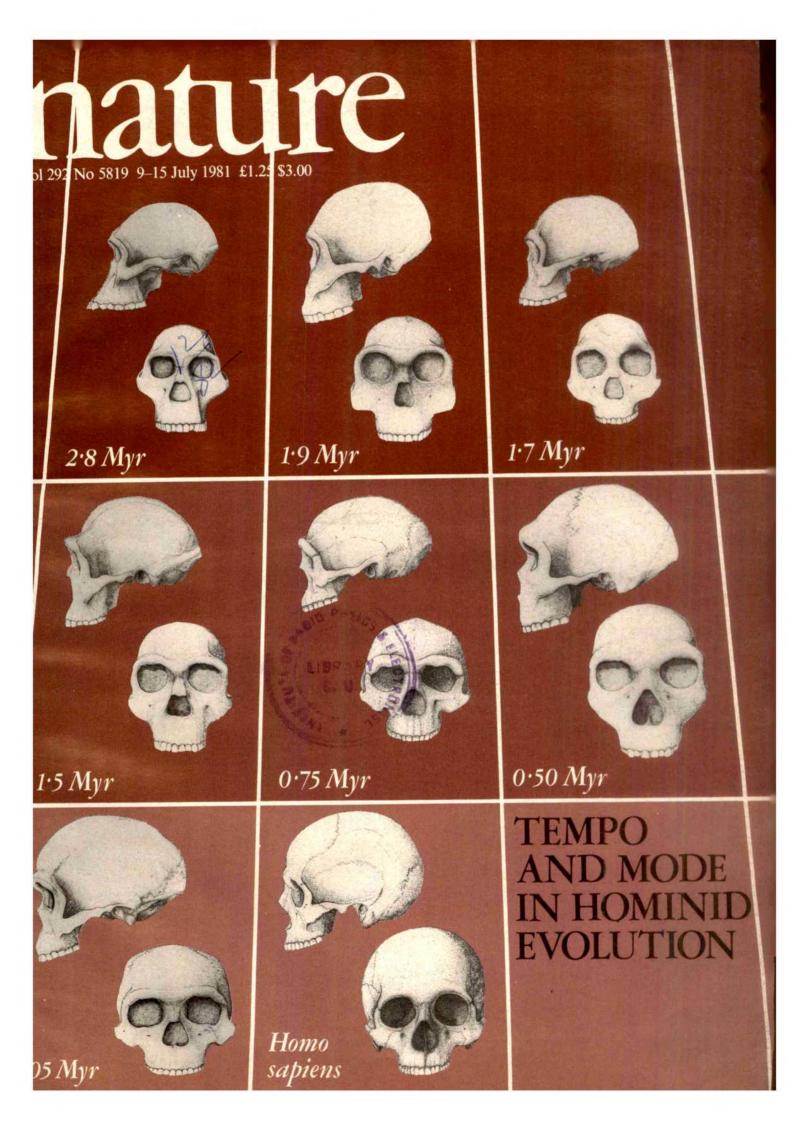

The PM-10AD is a triumph of inspired simplicity—a simplicity that means optimum results.

FOXY matches fractions to your chromatogram.

Not to the clock.

FOXY, the Fraction-Optimizing X-Y fraction collector.

Microprocessor-controlled collection techniques save you time and expand your research. You can program collection by absorbance peaks, timed intervals, counted drops, controlled output of an ISCO peristaltic pump, or by Volumeter discharges. FOXY's stainless steel racks hold practically any size test tube or 28 mm scintillation vials. For larger volumes, you can collect directly into 500 ml bottles or use a preparative adapter to obtain up to 72 fractions of unlimited size There's big capacity—up to 288 tubes—occupying mini-

board is only 21 cm wide. FOXY collects from two columns at once and stops flow between tubes and at the end of the run.

You can isolate peaks identified by elution times or detected by an ISCO UV monitor. Join peak detector and time window programming to capture only specific peaks emerging at preselected times.

Mix racks and volumes in a single run, based on peaks or time. Col-

Tim run, based

mal bench space: the key-

lect only desired peaks in one rack; put baseline effluent in another rack, in a single container, or divert it to waste. And FOXY can reject void volume before collection begins.

FOXY's splashproof, sloped keyboard is easy to see and use. Flashing cues prompt step-by-step programming. A code directs you to a correction table to quickly put errant programming back on track. FOXY's display offers continuous program information, including current tube number and time or drop count.

It costs only \$2295 to add FOXY to your staff. Call toll-free to learn more about ISCO's smart generation fraction collector: [800] 228-4250 (continental USA except NE). ISCO, Box 5347, Lincoln, Nebraska 68505.

How Britain runs its science...

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2 x 3ft. guide offers a comprehensive survey of the administration of British science, showing the interlocking relationship between science, engineering and medical establishments. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England. In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

IHE FAST UNE!

IgGsorb is the IgG adsorbing agent that won't keep you waiting. It removes antibody and antibodycomplexed antigen from solution in a mere 15 minutes!

Highly specific for binding the FC portion of IgG antibodies, IgGsorb is a lyophilized preparation of Protein A fixed to the cell walls of inactivated Staphylococcus

lgGsorb has more than speed too. It has long storage life. Its homogeneity can be assured. And it serves a variety of applications, in some cases replacing charcoal, double antibody, and other cumbersome methods of separation.

Plus, there's news. IgGsorb now comes in liquid form as well as drv!

SPECIAL OFFER! Try it yourself and see how fast IgGsorb really is. Order a 10ml vial for just \$19.00. Or a 100ml one for \$80.00. Because two hour waits you really don't need!

British Journal of IARMACOLOC

The most respected journal for those professionally involved in the pharmacological sciences.

Pharmacologists, like other scientists, have to cope with ever-increasing amounts of information. A publication which only includes papers of the highest standard and relevant to current pharmacological research is obviously required. The British Journal of Pharmacology is just such a journal.

Original papers, submitted from all parts of the world, examine every aspect of drug action.

Chemotherapy, systemic pharmacology, drug mechanics, pharmacokinetics. psychopharmacology, autopharmacology are all given extensive coverage. British Journal of Pharmacology is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

RPC-5 ANALOG

for Nucleic Acid Chromatography

After extensive research, development, and testing, BRL is now introducing RPC-5 ANALOG, a chromatography matrix with performance properties quite similar to the well-characterized RPC-5.1 RPC-5 ANALOG chromatography is a useful tool for analytical and preparative fractionation of:

- Bacterial plasmids and supercoiled viral DNA
- Cloned DNA fragments
- DNA restriction fragments
- Oligomers of ss-DNA and RNA (synthetic and natural)
- Complementary strands of restriction fragments
- Recovery of DNA from aggrose gels

¹Wells, R. D., Hardies, S. C., Horn, G. T., Klein, B., Larson, J. E., Neuendorf, S. K., Panayotatos, N., Patient, R. K. and Seising, E. (1980) Methods in Enzymol. 65, 372-347. The performance characteristics of RPC-5 ANALOG make it the resin of choice for molecular biologists interested in nucleic acid chromatography because it provides:

- High resolution
- High capacity
- Quantitative recoveries (milligram quantities)
- Rapid separations
- Reduced costs
- Ease of use

for DNA Plasmid Purification

RPC-5 ANALOG column chromatography is especially useful in the purification of plasmids from cellular lysates as illustrated in Figure 1. The resolution of the plasmid is so complete that BRL has been able to develop a rapid batch method that still yields plasmids of 99% purity (Table 1).

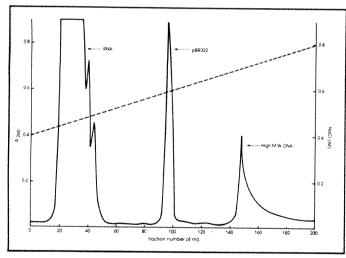

Figure 1. RPC-5 ANALOG chromatography of a total nucleic acid extract of a bacterial lysate from E. coll (HB101) harboring an amplified plasmid (pBR322). The nucleic acids were added to the column in 0.2 M NaCl, 10 mM Tris-HCl (pH 7.2) and 10 mM EDTA and eluted with an increasing linear salt gradient (0.4 - 0.8 M NaCl).

How Britain runs its Science

How the US runs its Science

These two new Nature wallcharts are now available.

The 2 x 3ft. guides offer a comprehensive survey of the administration of science in Britain and the US, showing the interlocking relationship between science, engineering and medical establishments. Designed as fold-out sheets, the

wallcharts can be carried easily to meetings or hung as posters for permanent reference.

The new 1981 wallcharts are available at £3.50 or \$7.95 each from Nature's offices in London, Basingstoke and New York.

D Marks

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). A draft abstract (50 words) is required.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

NEW

X-RAY **MICROANALYSIS** IN BIOLOGY

Edited by M.A. HAYAT

Professor of Biology at Kean College of New Jersey

June 1981; £30.00; 500pp; ISBN 0 333 32355 6

CONTENTS

Principles and Instrumentation — A.T. Marshall; Preparation of Specimens: Changes in Chemical Integrity — A.J. Morgan; Frozen-Hydrated Specimens — A.T. Marshall; Frozen-Hydrated Sections - A.T. Marshall; Sections of Freeze-Substituted Specimens - A.T. Marshall; Influence of Specimen Topography on Microanalysis — F.D. Hess; The Skeletal Muscle — M. Sjostrom; Liquid Droplets and Isolated Cells -J.V. Bonventre, K. Blouch and C. Lechene; Quantitative X-Ray Microanalysis of Bulk Specimens — F.D. Ingram and M.J. Ingram; Quantitative X-Ray Microanalysis of Thin Sections - G.M. Roomans; Index.

This is the first book dealing exclusively with x-ray microanalysis of biological specimens. It not only presents the basic theory and operation of the instruments used for producing, measuring and interpreting x-ray signals, but also describes in detail the preparation of bulk specimens, sectioned specimens and fluid specimens.

The book includes both qualitative and quantitative analysis of biological materials and it discusses application of x-ray microanalysis to pathology, physiology and cytochemistry.

Instrumentation is presented in a concise manner and methodology in detail. Almost all instruments are covered, including TEM, SEM and STEM. Instructions are given on how to produce, measure and interpret x-ray signals and emphasis is given to the aspects of instrumentation that are of practical use. In its comprehensive compilation of methods for preparing biological specimens the advantages and disadvantages of alternate methods are discussed.

READERSHIP: Electron Microscopy, Biology, Biochemistry.

LEVEL: Undergraduate and graduate students, researchers and research technicians.

British universities on the brink

The threat of execution is said to help to clarify the mind. The British university system, which has woken up to the threat of trouble ahead only within the past year, will not even profit by knowing where it stands from the announcement last week of the allocations of funds to individual universities for the three years ahead (see page 99). The dilemma is constitutionally appropriate. The University Grants Committee has dealt with the universities as it should — self-governing institutions as they like to think they are, they have been told to manage their own affairs as best they can within the funds made available for the next few years. But some options the universities are individually and collectively denied. Because the grants committee has coupled its financial allocations with specific instructions about the numbers of domestic and European Community students individual universities may in future accommodate, it will not be possible for them to work their way out of trouble by being more productive. (If ever the universities have time, the legality of this requirement might usefully be tested in the courts.) And because the universities that have come well out of the past week's lottery are unlikely, self-governing as they are, to throw in their lot with the less fortunate, it is probable that half a dozen of the places most seriously affected will have to sink or swim on their own. Some of them, faced with budget cuts of 25 per cent or so (Aston in Birmingham and Salford for example) will be lucky if they do not sink, and will even now be asking whether that is the surreptitious intention of either the government or the grants committee.

For while the committee's announcement last week will certainly leave its mark on the British university system, there are still too many loose ends for comfort. What will in the end most affect the universities whose budgets are most drastically to be cut will be the lack of any formal mechanism for paying off redundant members of university staffs. Although it is agreed that the universities on which the cuts fall hardest will be able to adjust only be getting rid of tenured academics, no funds are available for providing them with compensation. And although Dr Edward Parkes, the chairman of the University Grants Committee, told a House of Commons select committee last year that some £200 million would be needed to bring about the impending adjustment, merely £20 million has been set aside for such purposes (out of the universities' collective subvention). But should not academics suffer the indignities and impoverishments that seem certain to afflict some three million other unemployed people in the United Kingdom before the year is out? This is what the enemies of the universities are asking. Some such calculation may account for the spleen with which the government has pursued the universities since its election more than two years ago. The trouble is that tenured academics most probably have rights at common law against universities that dismiss them, and that the amounts involved will far exceed the sum that Dr Parkes has put aside. In the end, either the universities concerned will have to exercise the right of self-governing institutions to go bankrupt or they will have to be rescued with more public money than the government will save with the cuts now decreed.

Another conspicuous loose end is that the grants committee has delivered its advice ("instructions" is more appropriate) without saying how its decisions have been reached. Are the lucky universities those with the lowest unit costs, the best track records in research grant applications, the lowest staff-student ratios, the best records in the recruitment of students, or what? There are reasons why too detailed a disclosure of the criteria that have been used would be damaging to individual universities. As things are,

however, the committee should forgive those now unwillingly dependent on its allocations of funds for suspecting that often mere gossip or even prejudice has determined its decisions. This charge, no doubt a slur, is nevertheless inescapable. If it had been prudent, or even merely politically expedient, the committee would several months ago have invited universities to agree on the criteria by which its decisions should be made. Even if the universities had failed to agree among themselves, the result would have been a licence to do what has now been done. As things are, without having consulted in advance, Dr Parkes has put his committee in the unenviable position of being regarded by the universities — his strongest supporters — as a dispensable bulwark between themselves and the public purse.

Four other questions remain unanswered. First, is it right that decisions of such gravity for the universities should be made in the absence of a mechanism for settling policy on higher education as a whole (polytechnics included)? Second, should British taxpayers be expected to put up with apparently arbitrary limits on the provision of university education, regardless of the ability and the willingness of qualified institutions to provide it? Third, what will be the consequences of last week's decisions for the pattern and even the quality of research? Finally, is it now to be supposed that higher education has become, as educationists have become too fond of saying, "irrelevant"? These questions will be much discussed in the months ahead.

Promising Americans

The United States Administration will not lightly be forgiven for the hash it has made of plans for international collaboration in this year's budget. President Ronald Reagan's budget director, Mr David Stockman, seems just the kind of man to implement a promise "to get the government off the people's backs". It is also a technical triumph that he and his colleagues were able to produce a coherent replacement for President Carter's budget during their few weeks in limbo, between the election last November and Inauguration Day. But in the process the budget team was plainly unreasonably dismissive of the consequences overseas of its proposals. And while Congress is doing what it can to repair some of the damage, at this stage it cannot put everything to rights. Certainly Congress will not be able to exorcise the impression that overseas obligations take second place, in the evolution of United States strategy, to domestic exigencies.

The trouble is well illustrated by two very different examples from the budget for the next financial year (which begins on 1 October). First, and simplest, is the case of the overseas budget of the National Science Foundation, used largely for supporting a surprisingly modest programme of direct collaboration overseas. (That large funds are still to be spent by other agencies, the State Department for example, is beside the point.) Like the foundation's educational budget, the overseas programme was drastically curtailed in Mr Stockman's budget. Nobody seems to have appreciated that the National Academy of Sciences was counting on this part of the foundation's budget for its contribution to the International Institute of Applied Systems Analysis, of which it is (with the Soviet Union) the principal member, and from which it is required by its obligations to give a year's notice of resignation. It now seems likely that the House of Representatives has found a way of letting the foundation dispose more flexibly of its budget, so that the academy will not have to

take a begging-bowl around to pay its dues on 1 January, but the future of its contributions remains in doubt. Mr Stockman may have concluded that the United States derives little benefit from the work of the international institute (which is probably true) and that even the institute's disappearance would be welcome (which may also be true). But international obligations cannot be overturned as easily as that. If they were formal treaties, duly ratified by the Senate, no budget director would think of striking out the associated costs. Do agreements on scientific collaboration deserve less careful consideration?

The trouble about the United States commitment to the International Solar Polar Mission is a different case. This potentially valuable scientific exploration of the Sun away from its equatorial plane has been planned for the past several years between the European Space Agency and the National Aeronautics and Space Administration, each of which was to have launched a satellite. There were howls of protest from Paris when Mr Stockman's budget omitted this item (see Nature 5 March, p.1) and science administrators in Western Europe have since fallen into the habit of complaining to their opposite numbers from the United States whenever they encounter them. Indeed, the Europeans are in danger of making too great a fuss; what is at stake is a single if expensive project, not an understanding affecting the survival of an institution, and in any case a single satellite in a polar orbit about the Sun at the next solar maximum will be a lot better than none. Even here, Congress is doing what it can to help (see page 102). It remains to be seen how the issue will be decided — but surely there are no grounds for flirting with the resuscitation of the Halley mission (in which every agency in the world capable of launching spacecraft will be participating) while a smaller sum of money would help to fulfil an international promise.

From the frying pan ...

The battle for the control of the British telecommunications network is almost over; there is a decent chance that the bill with which Parliament has been struggling for the best part of a year will become law in the next few weeks. But the war is only now beginning. In the past few weeks, several groups of private interests have been cheekily staking claims to set up in competition with the telecommunications monopoly. Cruelly as it must seem to the public monopoly (trendily known as British Telecom), other British public monopolies and nationalized industries are prominent among the would-be vultures. Thus British Rail (a wholly owned nationalized industry) and British Aerospace (wholly owned until nearly half its shares were sold off earlier this year) are talking of using the railway network as the başis for a competing trunk telecommunications network. Even more cheekily, Cable and Wireless, the state-owned company originally set up to operate telephone networks overseas, is talking of entering the domestic market even though it has not yet been sold off to the public (as the government intends). Yet British Telecom is plainly not intending to put up with whatever indignities the months ahead may bring. Some weeks ago, it put out a sombre warning of the dangers of connecting to the existing telephone network terminal equipment supplied by others than itself. Last week, it published a much more intelligent document a reply to the study commissioned by the Department of Industry from Professor Michael Beesley, which concluded that no great harm would be done, but rather good, if private interests were allowed to rent circuits from British Telecom and to use these for providing services that could then be resold to others (see Nature 23 April, p.619). The argument will now begin.

The resolution of these and related issues is crucially important for the future use in Britain of a technology as full of promise as politicians have been saying this past long year. And what happens in Britain may even be instructive elsewhere; experience in the United States of the erosion of the Bell System's monopoly is not everywhere valid and is in any case confusing, while governments elsewhere in Western Europe are in much the same state of indecision as afflicts the British government. But the

British experience is likely to be less helpful than it might have been. The most reprehensible feature of the Telecommunications Bill is that nobody will be allowed to chip away at the British Telecom monopoly without the consent of the Department of Industry. In practice, it will be for civil servants and British Telecom between them to decide what shall be allowed and what prohibitied. Thus although the present government has promised that within three years others than British Telecom will be entitled to sell terminal equipment to telephone users (and the illicit trade is already gathering strength), a change of government could change all that. And the latest document from British Telecom, intelligent though it is, demonstrates again what has been clear all along — that there is an urgent need for an explicit set of rules and some independent tribunal for administering them.

What Beesley said was simple. British Telecom would not come to a sticky end if it were required to follow the practice forced on the Bell System in the United States, and to lease trunk circuits from its own network to private operators who might then resell telephone services. Everybody's model is the American company MCI Communications Inc., whose customers are able to make trunk telephone calls between many (but not all) cities in the United States for roughly half the cost charged by Bell. Beesley acknowledged that such arrangements would rob British Telecom of revenue but not necessarily of profit, and argued that the business is not, in any case, a zero-sum game - symbiosis between the rump of the monopoly and private operators is just as likely as out and out parasitism of British Telecom. British Telecom protested at the time that Beesley's recommendations would "skim the cream" from its own business, and repeats that argument in last week's document — but in an especially revealing way. It repeats its fear about the cream, asserts that leasing its network to others would not improve the technical quality of services provided to customers (which is untrue) and goes on to say that such arrangements would compel it to "rebalance its tariffs in order to make individual sectors pay for themselves". The simple answer to the last complaint is "Whyever not?" But British Telecom is counting on the unwillingness of British politicians to fall in with "rebalancing" if the result means higher charges for any important sector of the British electorate.

The government has only itself to blame for the embarrassment it will now be caused. British Telecom, in its reply to Beesley, is disarmingly open about its present practice. It charges extra for use of the trunk network so as to subsidize local telephone calls and rural telephones. It urges the "material benefits" of providing a uniform service at uniform prices, and says that one of the consequences of liberalization would be increased rentals for telephone lines, "hitting hardest at the less well-off customers who make the fewest calls". Just in case the government fails to get the point, British Telecom guesses that the cost of a telephone call from a public coinbox would increase fourfold. Politically, the argument is telling. It is, however, false. The annual accounts of British Telecom are at present most obviously distorted by the government's requirement that the monopoly should finance the development of its network mostly out of current revenues. If the government decided otherwise (as it should) all tariffs could be reduced. But there is in any case no justification for the present distortion of telecommunications tariffs by British Telecom's self-assumed social obligations. Why should the interests of the telephone users "who make the fewest calls" increase the telecommunications costs of more serious users, mostly from business and industry? British Telecom should instead be required to follow economic pricing policies - charges for different services related to their marginal costs Parliament then invited to pay for socially valuable but otherwise uneconomic services (as is already done with railway services). The difficulty is that none of this can be accomplished without an independent and public examination of what the costs should be. The government itself is not sufficiently expert and is politically too suggestible. Thus the ironical outcome of the first serious attempt to liberalize the British telecommunications monopoly is likely to be to put the clock back ten years, and to throw the management of these vital services back into the political arena.

Congress stirs non-proliferation row

Testimony on Iraq raid backfires

A serious row affecting the future of the Non-Proliferation Treaty has broken out between the United States government and the International Atomic Energy Agency in Vienna. At issue is the appearance before two congressional committees in the past two weeks of a defector from the agency's safeguards inspectorate, Dr Roger Richter (33). At a meeting of the board of the agency in Vienna this week, Dr Sigvard Eklund, director-general of the agency, said that Dr Richter's evidence to the Senate and House committees on Foreign Relations (on 18 June and 1 July respectively) had involved the disclosure of confidential information in breach of his contract of employment, and that the agency was taking legal advice.

Dr Richter's appearances have been dramatic, to say the least. According to Dr Eklund's statement on Monday, Dr Richter last showed up for work in Vienna on 15 June. The following day, Senator Alan Cranston, chairman of the Senate committee on Foreign Relations, announced in Washington that Dr Richter, having resigned for the occasion, would be giving evidence three days later. Dr Richter's resignation was received by telex in Vienna on 18 June, according to Dr Eklund; it was not, however, accepted, but Dr Richter was instead fired.

Dr Eklund in his statement said that Dr Richter had worked for the agency since February 1978, and that he had been assigned to the section of the agency concerned with supervising safeguards in the "south and south-east" sections of the agency's territory, including both Iraq and Israel, in March 1979. Dr Richter's evidence to the congressional committees consisted most conspicuously of the assertion that the agency's safeguards were not adequate to detect violations of the Non-Proliferation Treaty by Iraq.

Dr Richter was dissuaded by Senator Cranston from quoting from a letter he had written a year ago to the US State Department, in which he had alleged that "the IAEA safeguards are totally incapable of detecting the production of plutonium in large scale materials-test reactors..." such as that destroyed by the Iraeli raid on Tamuz on 7 June.

One of the reasons why the agency has taken umbrage is that neither house of Congress has taken its denials seriously. On Monday, Dr Eklund told his board that the authorities in Iraq had been approached immediately after the Israeli raid on Tamuz

and visited the site on 18 June. They were unable to visit the main reactor because of the extent to which it had been damaged (and the insistence of the Iraqi authorities on a personal accident indemnity). The associated research reactor and the stockpile of enriched uranium was however inspected and found in order.

For the agency, the incident obviously raises serious questions about the fiduciary responsibilities of its safeguards inspectors. One requirement of the Non-Proliferation Treaty is that information gathered by inspection teams should be kept confidential. The fact that a defecting inspector should have told all to Congress on the day of his formal resignation is a serious blow to the system.

In the United States, Dr Richter's evidence to the Senate and the House has had an equally profound effect, and may impede the Administration's declared intention of liberalizing restrictions (made necessary by the Carter Anti-Proliferation Act) on the export of nuclear technology. The nuclear industry has been especially critical of the act's requirements that

recipient nations, even those that had signed the treaty, should go further than merely accept the Vienna safeguards before becoming eligible.

Part of the reason why the Carter Act has been controversial among potential recipients of United States' nuclear technology is that one condition for their signature of the treaty, in the early 1970s, was the promise that nuclear powers would assist with the development of peaceful nuclear technology.

Opinion is divided in Washington about the strength of Dr Richter's testimony.

In Congress, however, Senator Charles Percy, chairman of the Senate Foreign Relations Committee, says he has been shaken by Richter's evidence.

The chief casualty is likely to be the Administration's determination to reform the anti-proliferation policy it inherited in February. Even President Reagan startled the nuclear industry when he acknowledged at last week's press conference that signature of the Non-Proliferation Treaty did not necessarily imply compliance.

British universities transformed by budget

A major reshaping of the British university system was decreed last week, when the University Grants Committee sent letters to each of the 51 universities in Britain giving details of their recurrent grants for the next three academic years. But the full implications of what the committee has decided will not be clear until the details have been analysed by the Committee of Vice-Chancellors and Principals, to which the universities have separately (but in confidence) provided copies of the letters they have received from the committee.

Two features of the new pattern are however apparent. By the beginning of the academic year 1984-85, the total number of students from the United Kingdom and elsewhere in the European Community is to be no greater than 249,000, five per cent less than last year (the base year for all the committee's calculations) and 7.5 per cent less than in the current academic year. And the total recurrent grant for the universities, paid on the recommendation of the University Grants Committee, will fall from £972 million in the current year to £808 million in 1983-84.

As well as publishing a general statement of what it was about, the committee last week sent individual letters to universities including what is called "advice" about the teaching activities that should be continued (and sometimes strengthened) but also, in many cases, abandoned. Most recommendations of this kind, which only the bravest universities will ignore, concern the arts or social sciences. But some universities have also been "invited" to

abandon teaching their brand of biology.

The University Grants Committee (which has no formal mechanism for dealing with enquiries from the press) is not prepared to say how its decisions about individual universities have been arrived at. It seems, however, to have sought to preserve excellence and minority areas of study and to encourage what is known as "thrift" while maintaining regional balances. Unit costs appear to have been influential in the case of the University of Bath which, while boasting of a diversified programme of studies linked broadly (and sometimes loosely) with industry, also boasts of the lowest costs per student in Great Britain, and has been the most generously treated university of all - its income is cut by merely 7 per cent

It is also known that the committee, in making specific recommendations to the Department of Education and Science for grants to individual universities, took advice about the performance of universities in competition for research grants from the research councils. One vice-chancellor, at least, is glad to think that his university's relative immunity from impending frugality stems from his academics' success in raising more than £3 million a year by way of grants.

Vice-chancellors at the newer technological universities most severely affected by the cuts complain, however, that in its calculations of external research support the grants committee has paid too little attention to research support provided by industrial companies as distinct from research councils. They also

© 1981 Macmillan Journals Ltd

point, with justifiable surprise, to the committee's formal endorsement (in its letter for general circulation) for courses of study intended to foster closer relationships between students and industry and the presence of at least three former colleges of advanced technology ("universities in waiting" in the early 1960s) among those now worst hit (Salford, Aston in Birmingham and Bradford).

The delivery of the committee's letters to universities comes at an awkward time, with the summer vacation almost everywhere begun. The committee has agreed that aggrieved universities should have a right of "consultation", which will, nevertheless, have to be exercised quickly. The committee of Vice-Chancellors and Principals is hoping within the week to put together a document showing how the pattern of the university system will be changed, but even that calculation will be jeopardized by uncertainty about the recruitment of overseas students (who pay higher fees) in the next few years. Even moderately gloomy forecasts suggest that the total reduction of university income may be as much as 17 per cent when allowance is made for that deprivation.

French universities

New appointments

While Mrs Margaret Thatcher squeezes the British universities, the departure of another lady over the channel has French universities sighing with relief. Madam Saunier-Seîté, Minister of the Universities under President Giscard d'Estaing, set out to centralize power over appointments and the allocation of degrees, and to weaken the role of some of the smaller regional universities. Now, under a gentlemanly new minister of the new government, M. Alain Savary, that is being reversed.

M. Savary says he wants dialogue with the universities, and dialogue he seems bound to get. Within a few days of the election of President Mitterrand, 100 lecturers at the University of Paris signed a declaration condemning the previous minister's "scandalous" methods of making university appointments and demanding a more democratic approach. The two principal education unions, the Syndicat National de l'Enseignement Supérieur and the Syndicat Général de l'Education Nationale, also weighed in with a joint statement warning that conservative and technocratic forces were still in control of the universities, and that they would have to be overthrown.

The chief target seems to be the Conseil Supérieur des Corps Universitaires, which according to its timetable should meet this month to consider this year's new appointments to the few university posts available. The council, strengthened by Saunier-Seîté, interviews candidates and makes its decisions in private, without right of appeal, complain the Paris 100; moreover

its council is said to be predominantly conservative and to give a poor hearing to candidates offering a novel approach to teaching or unfamiliar combinations of subjects. Certainly, the council — as now constituted — is an obstacle to university autonomy, and M. Savary, while not referring to it directly, has said he wishes to restore university autonomy and to set up new decision-making methods which will be "very decentralized".

On another tack, Savary also seems set to restore some of the second and third-level degree courses whose status as such was removed by the previous minister. A partial list of approved courses for 1981-82 was released last week. It was determined almost entirely by assessment procedures set in train the previous year and, conscious of its shortcomings, M. Savary has announced that the universities are free to appeal against the decisions (where a course has been cancelled) or to make new proposals. But he has called for "a sense of self-discipline" among the professors: there is not to be a free-for-all in which every wild proposal will meet approval.

Savary also says that appeals may not last into next year. The device is a stop-gap measure. For the long term, M. Savary plans to enter "without delay" into discussions, with all who are interested, over new mechanisms for the accreditation of courses.

Robert Walgate

US biomedical research

Against the tide

Washington

Democrats in the House of Representatives have been having little success in trying to reverse budget cuts proposed by President Ronald Reagan, but they may gain a rare victory on the issue of support for biomedical research training.

Focus of the dispute is the National Research Service Awards (NRSA) scheme, which provides about 10,000 grants annually to support postgraduate and postdoctoral research workers. The Reagan Administration is proposing that such grants should no longer contain institutional support to cover general overheads at research institutions, which would mean a cut of more than 25 per cent in grant allocation. Medical schools and universities complain that without this support — about \$50 million a year — they will not be able to sustain an adequate base across all areas of research training.

The medical schools won a preliminary round earlier this year, when both houses of Congress rejected the Administration's proposal to drop institutional support provided through the awards scheme as a budget saving for the fiscal year 1981, which began last October.

Less expected was their success in the debate on the 1982 budget in the House. The defection of a number of conservative Democrats to the Senate side resulted in

defeat for proposals submitted by the House leadership, and victory for amendments presented by Republicans.

For example, the House Science and Technology Committee had proposed deleting funds for the construction of the liquid metal fast breeder reactor at Clinch River in Tennessee, transferring much of this money to research in solar energy and conservation. The full House, however, rejected this proposal, restoring the Clinch River funds and severely reducing the solar energy budget.

In biomedical research training, however, the cuts proposed for 1982 brought a stream of protests from the research community. In a letter to Representative John D. Dingell, chairman of the House Energy and Commerce Committee which has responsibility for the budget of the National Institutes of Health, 58 separate medical and research associations warned that the cuts would be "severely harmful".

The lobbying seemed to pay off. Mr Dingell's committee recommended to the full House that the NRSA budget be raised to \$194 million from the proposed \$147.3 million.

The Republican-run Senate, however, has already passed a budget bill containing the lower figure proposed by Mr Reagan. In addition, the Senate suggests an upper limit on biomedical research supported by the National Institutes of Health of \$3.7 million, a move which the medical associations describe in their letter as "arbitrary, unprecedented and unnecessary."

Negotiations now have to take place between the House and the Senate before both sides can agree on a common bill. At the same time, there is a parallel debate going on over the budget for the Department of Health and Human Services which is responsible for the funding of the National Institutes of Health.

In particular a key Senate Committee — Labor and Human Resources — is in deadlock. The committee's previous chairman, Democrat Senator Edward Kennedy, backed by other Democrats and two Republicans, is proposing an additional \$50 million for research training awards. The current chairman, Republican Senator Orrin Hatch, is opposed to the committee taking a public stance in defiance of the President's recommendations; but he has promised that if the committee approves the lower figure, he will intervene to see if it can be raised.

Medical school lobbyists, such as the American Association of Medical Colleges, intend to keep up the pressure to have the funds restored. Dr Lamont-Havers of the Massachusetts General Hospital told a meeting of the American Association for the Advancement of Science that the proposed cuts reflected "a deep bias within the Office of Management and Budget" against the biomedical research training programme.

David Dickson

UK atomic energy

Design delays

British hopes of building a pressurized water reactor (PWR) seem now to rest on Dr Walter Marshall, chairman of the UK Atomic Energy Authority, who was last week appointed by the Department of Energy as chairman of a "task force" intended to stifle squabbles about the project — and to help reduce the cost. This development is a consequence of mounting impatience among Marshall and his colleagues on the four-man "nuclear industry group" with the delays that have accumulated in the PWR programme; they put their complaints in a letter to the Department of Energy three weeks ago.

As yet, the National Nuclear Corporation—the putative constructor—has not completed the reactor design, which should have been sent to the Nuclear Installations Inspectorate in the spring. Like a schoolboy late with his homework,

Marshall the catalyst

the corporation was able to manage by the deadline only a "reference design" that omitted details of the containment vessel and the emergency core cooling system. The missing information has not yet materialized because the corporation (and the Central Electricity Generating Board, which will have to pay for the reactor) have had cold feet about the cost.

Several modifications of the basic Westinghouse design have added to the cost. The generating board has asked for relatively easy access to the steam supply parts of the system to reduce maintenance time and the radiation exposure of workers. The containment building for the reactor was intended to have a double-walled construction, some concrete shielding was intended to be extra thick and there were to have been four (rather than two) emergency core cooling systems.

However, critics of these changes say they substitute concrete and equipment for analysis. Good chemical control of the steam supply system — for example, by purging the steam supply system before

dismantling for refuelling — can reduce radiation doses to levels acceptable to the generating board, say the critics, without using more concrete. (The board has indicated that it will not accept levels higher than those at the Heysham advanced gascooled reactor, a relatively clean power plant.) Some American utilities already use the hydrogen peroxide method in their PWRs. So this week a team of National Nuclear Corporation and generating board scientists has flown out to inspect such "best practice" in American reactors, and make its own measurements of radiation.

Similarly, the net benefit of quadrupling the emergency core cooling system could be obtained more cheaply by looking closely at the failure rate and significance of individual components of the system. The containment building will also probably be simpler, and similar to the optional construction designed by the Bechtel Corporation which is acting as consulting engineers to the National Nuclear Corporation.

What has worried Marshall, and now apparently the Department of Energy, is that the pursuit of perfection at the National Nuclear Corporation has been time-consuming as well as potentially expensive. His task force will function not as a decision-making body but as a forum in which the designers can be shamed into making up their minds.

All of the questions to be tackled relate to safety, and most of them involve trade-offs against cost. Marshall hopes that the outcome will be a reactor with a construction cost (per kW of generating capacity) only 60 per cent of the cost of the advanced gas-cooled reactor. He may have to be satisfied with less. Although some of the refinements of the Westinghouse design may have to be abandoned, Marshall is confident that the reactor can be built within British safety criteria.

The plan now is that the final design should be with the nuclear inspectors in the autumn. With a lot of luck, it may still be possible for the government to hold its promised public inquiry on the project before the end of 1982, almost exactly a decade after the electricity board first designated the site at Sizewell for the project. Marshall's chumminess with the minister at the Department of Energy with special responsibility for nuclear energy, Mr Norman Lamont, will help to simplify the timetable. Robert Walgate

Large Space Telescope

View from Munich

The contract for the European Coordinating Facility for the Large Space Telescope has been awarded by the European Space Agency (ESA) to the European Southern Observatory (ESO) in Garching, near Munich. The other contenders for the prize were the Royal Observatory at Edinburgh, the Institute of

Soviet second sentences

Dr Andrei Sakharov has this week issued two new appeals to scientific colleagues abroad on behalf of fellow human-rights activists.

The first is on behalf of Aleksandr Bolonkin, a mathematician arrested in 1972 on a charge of disseminating false propaganda - in fact, for having circulated the samizdat "Chronicle of Current Events". For this, Mr Bolonkin received a sentence of four years' prison camp and three years' internal exile, while the state Attestation Committee refused to confirm his doctoral degree. After serving his time in camp, and just before the sentence of exile expired, Bolonkin was rearrested and sentenced to a further three years in the camp. Then, a few weeks ago, just ten days before this second sentence was to expire, he was charged again.

Such reconvictions of political prisoners due for release have been frequent in the past two to three years, and many now fear that such a fate may await Dr Sergei Kovalev, whose seven year prison term (on the same charge as Bolonkin) expires next December (to be followed by three years' Siberian exile). Kovalev, whose life is reported to be in danger, is the subject of Sakharov's second appeal, which takes the form of an open letter to Dr Linus Pauling. Included in the appeal are Tanya Osipova, Dr Kovalev's daughter-in-law and a member of the Moscow Helsinki Watch Committee, who was recently sentenced to 5 years labour camp and 5 years exile, and her husband, Ivan Kovalev, against whom it is understood similar charges of subversion are being prepared. Tanya Osipova's plight, says Sakharov, is particularly serious, since she has to serve her sentence in an ordinary criminal camp, whose regular inmates traditionally bully and exploit the political offenders to gain favour with the camp authorities.

Space Astrophysics at Frascati and the Institut d'Astrophysique and the Observatoire de Paris in a joint proposal.

ESO (whose member states are Sweden, Denmark, the Netherlands, Germany, France and Belgium — to be joined by Italy and Switzerland next year) moved last year to the Munich site from Geneva. It manages the observatory at La Silla, Chile, where the main instrument is a 3.6-metre reflector.

There is more than enough room at Garching for the space telescope institute. ESO now operates an imaging processing unit, incorporating a VAX 11/780 computer. Another VAX is to be installed, along with 15 staff members, who will be expected to spend half their time on their own research and half on coordinating the European space telescope observations.

The detailed arrangements for the use of the telescope have yet to be worked out between the US National Aeronautics and Space Administration (NASA) and ESA.

ESA's decision has ruffled several British feathers. The Edinburgh proposal was based on the Starlink image processing system, which also uses the VAX computer and links six British universities. A confidential report by an ESA subcommittee, set up to evaluate the proposals, is said to have highlighted the scientific merits of the British scheme but put it in second place because the location was "far off from most member countries". Problems with pay differentials and apparent weaknesses in management and archiving were also mentioned, but these objections are dismissed by some British astronomers, who consider that a system based on Starlink would provide the best facility for European astronomers. Such a system could, however, be developed with advantage at ESO. Philip Campbell

Curien on top

The council of the European Space Agency (ESA) has unanimously elected Professor Hubert Curien, president of the Centre National d'Etudes Spatiale, the French space agency, to be its next chairman. In a break with tradition, the council has also elected two vice-chairmen Dr Harry Atkinson, a British delegate to ESA, and Dr H. Grage, a Danish delegate. The hope is that the three new appointees, who represent separate national interests, will between them steer the agency onto a truly European course as it negotiates its future for the next ten years.

Despite the unanimous vote, however, Professor Curien's election was not without dissent, some delegates fearing that it might give too much weight to French arguments for the further development of the Ariane launcher. Britain had argued that it was time for a British chairman. the last one having been Sir Harrie Massey who chaired the European Space Research Organisation, ESA's predecessor, in the early 1970s. But other countries feared that the possible British candidates would be too partisan. An attempt by Italy and Switzerland to bring John Adams, ex-joint-director of CERN, the European centre for high-energy physics, into the competition failed on the grounds that he is not a delegate to the ESA council. John Adams had declined to apply for the post of ESA's directorgeneral when it became vacant last year.

In the event, the compromise has been to elect the British and Danish vice-chairmen to work with Professor Curien. With the current uncertainty over ESA's future programme, they are bound to play a more vital role than ESA chairmen in the recent past.

Judy Redfearn

US space research

Halley again?

Washington

A faint glimmer of hope that there may, after all, be a mission to Halley's comet filtered from the House of Representatives last week. The House has voted to include \$5 million in the budget to keep the project alive during 1982. But this is less than the \$25 million which scientists at Jet Propulsion Laboratory (JPL) of the National Aeronautics and Space Administration (NASA) say is necessary in the 1982 budget for the first stage of a \$350 million project.

The Republican-dominated Senate in passing a parallel bill last month did not include money for a Halley mission because it had not been requested by the Administration. Even if the proposed mission survives the compromise bill which the two legislative bodies must now negotiate, it still has to go through the appropriations process in which budgets rather than programmes are agreed.

Scientists at JPL are hoping to convince President Ronald Reagan that not mounting the mission would be a serious blow to national prestige, given that the European Space Agency (ESA), Japan and the Soviet Union (in partnership with Comecon countries and France) are preparing their own plans.

Dr Ray Heacock, JPL's choice as project manager for the Halley mission, said last week that the \$5 million would be sufficient to fund the project for the first three months of the next fiscal year. After that the President, if the mission is approved during negotiations on the 1983 budget for the agency, could direct NASA to reprogramme some of its 1982 funds.

The proposal has some strong supporters, particularly among those who feel that space science activities in NASA have been unfairly squeezed by the agency's preoccupation with the space shuttle.

The original plans have also been scaled down considerably. NASA had initially talked of a spacecraft which would travel alongside the comet on its way to a rendezvous with the smaller Tempel 2 comet. The latest plans are for a more modest mission using reserve equipment from previous planned missions to launch a spacecraft through the comet's tail within 600 to 1,000 kilometres of the nucleus.

There remains hope, however, that NASA may at least be able to resurrect its full participation in the International Solar Polar Mission, originally planned to fly two spacecraft in complementary orbits over the poles of the Sun. The agency's decision, at the prompting of the Office of Management and Budget, to eliminate funding for one of the spacecraft generated a storm of protest from European allies which are building the other.

The House authorization bill passed last week added \$15 million over the Admini-

stration's request to allow NASA to continue construction of its spacecraft. This decision is likely to be supported in negotiations with Senate counterparts, where exastronaut Jack Schmitt is responsible for overseeing NASA programmes. The recommendations from the Appropriations Committee would also permit the project to continue, and given the importance which top State Department officials have attached to maintaining international commitments, it seems unlikely that the Senate Appropriations Committee, which meets to discuss NASA's budget next week, will object.

At the same time, NASA is unlikely to accept ESA's offer to build the second spacecraft, made during the negotiations to salvage the mission. Representative Don Fuqua, chairman of the House Science and Technology Committee, said that he was opposed to this proposal, because it was unfair to expose European contractors to the vagaries of US policy, and because even though the price-tag would be lower. spending the money in Europe would still result in a loss of US jobs and profits. TRW, the company selected by NASA as contractor for its own spacecraft, is now said to have found ways of reducing its costs considerably, a move likely to increase the mission's chances of survival

David Dickson

Trypanosomiasis

Question of breeding

Schemes for breeding cattle resistant to trypanosomiasis are to be hatched at a research institute being planned in the Gambia (West Africa) with support from international aid agencies and foundations. The objective is to throw light on why N'Dama cattle in Africa appear to be genetically more resistant to infection by trypanosomes (also the infectious agent of African sleeping sickness) than are the more common Zebu cattle, and to find ways of propagating this resistance.

Much of the enthusiasm for the new institute comes from the President of the Gambia, Sir Dawda Kairaba Jawara, who was trained as a veterinary surgeon in Glasgow in the early 1950s, and who became leader of the People's Progressive Party in 1960. A preliminary meeting was held at Bellagio last year, and a meeting in the Gambia in May this year worked out a timetable on which further decisions must be made in time for a final decision about the project by January 1982.

Among international research projects, the Gambian research centre is unusual in that the African Development Bank seems to be prepared to take the lead in providing funds. Other interested parties include the European Community and the British government, the Food and Agriculture Organization and the World Health Organization of the United Nations, and research institutes in the World Bank

network, including the International Laboratory for Research in Animal Diseases in Nairobi. A technical appraisal of the project is being carried out this month in the Gambia, and should be completed in October.

The mechanism of trypanotolerance in N'Dama cattle is far from clear. The capacity for tolerance obviously has a genetic basis, but the older cattle are the more free from trypanosomes in the blood, suggesting that tolerance is acquired in response to trypanosomal antigens — and that even N'Dama cattle might benefit from multiple vaccines. Part of the intended research programme will be to look for genetic markers for the easy identification of resistant cattle. The long-term objective is to prepare the ground for setting up breeding centres for the propagation of potentially resistant cattle.

The initial costs of the centre are estimated at \$3.5 million, with annual running costs of \$1.5 million.

Bulgarian wildlife

Shooting for keeps

Plovdiv

Bulgaria, which this year is celebrating its thirteen hundredth anniversary of statehood, has for a number of years been committed to an ecological policy aimed at restoring its range of wildlife to the level indigenous in the country a millenium ago. During the past few years, extensive herds of roe and red deer have been built up, moufflons have been reintroduced and a small herd of bison has been established based on stock remaining from a former royal park. And now, during the past month, a second herd has been formed in the national game and forestry park at Preslav; fourteen animals, including four pregnant cows, were transferred from the existing reservation and will eventually be joined by animals from Poland and the Byelorussian SSR.

This faunal re-establishment policy is part of an overall reafforestation drive. During the long Turkish occupation, which ended just over a century ago, a large proportion of Bulgaria's primaeval forests were destroyed. But shortly after the establishment of the Bulgarian People's Republic in 1944, a major tree-planting programme was started and considerable attention given to conservation. During the Second World War, Bulgarian game herds multiplied virtually unchecked, so that stocks became sufficient for the new regime to incorporate into its forestry policy a role for the human gun-bearing predator.

According to a report presented last month at the Plovdiv symposium on "Wildlife and the Environment" (part of the "Expo-81" World Hunting Exhibition), this policy is working well. Although every adult Bulgarian citizen is entitled to join the Hunting and Fishing

Union, thereby acquiring the right to hunt game, stocks are flourishing. The latest census gives 14,000 red deer (which have spread to almost all suitable habitats throughout the country), some 117,000 roe deer, which have moved permanently into arable areas and established a field ecotype, some 30,000 wild boar, 2,700 fallow deer, 2,000 moufflons, 1,500 chamois and 700 bears.

However, some small game species have suffered, apparently because of changing ecological conditions. The hare population, in particular, suffered a considerable decline in the late 1970s. The Hunting and Fishing Union, however, implemented a strict conservation plan—which included a total ban on hunting for two years—and the latest figures show a considerable increase.

Managing forests as a combined hunting and conservation resource does not seem to produce major conflicts of interest in Bulgaria. The various hunting clubs affiliated to the Hunting and Fishing Union are assigned specific tracts of the state forests, and are expected to assume many of the traditional duties of the gamekeeper - including the distribution of fodder in hard winters. No paid keepers are employed - the club members perform such tasks on a voluntary rota basis, which gives them a good insight into the problems of forest management. (Foreign tourist hunters, of course, are provided with the normal complement of beaters and ghillies at the cost of some £500 per week.)

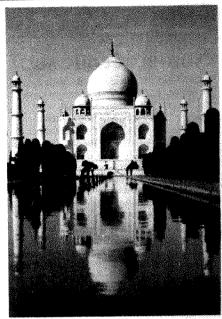

Nevertheless, Bulgaria has not been free from ecological mistakes in recent years, and this makes experts wary of introducing totally new species. Some years ago, for example, it was proposed to introduce American trout alongside the native Bulgarian variety, with which, it was confidently predicted, they would not compete. In the event, however, the newcomers attacked and virtually wiped out the local trout. Nevertheless, Bulgarian fisheries experts are prepared to consider innovations, and have reported some success with the bester - a non-migratory hybrid of beluga (white sturgeon) and sterlet, first produced in the Soviet Union about ten years ago.

India's environment

First steps

New Delhi

To protect the world-famous Taj Mahal, the Indian government is to close two coal-fired power stations in Agra, about 85 kilometres from the capital, New Delhi. This is one of the first concrete actions of India's new Department of Environment, aimed at saving the seventeenth century white-marbled monument from being blackened by smoke billowing out from the power stations. The new department has also persuaded the railway authorities to switch from coal to diesel power in their Agra workshops.

Agra's penance

These actions seem to be only a beginning for India's environment programme. According to the Ministry of Agriculture, some 175 million of the country's total 304 million hectares of land are subject to environmental problems. These include serious water and wind erosion over 150 million hectares, and shifting cultivation, waterlogging, saline and alkaline soils in the remaining area.

India is annually losing more than 6,000 million tons of topsoil through water erosion, and the total area subject to periodic floods now stands at 40 million hectares, an increase of 100 per cent in the past 10 years. Soil erosion is causing premature silting-up of tanks and reservoirs in which India has invested a massive \$12,500 million.

Another major problem is the large-scale deforestation in the Himalayas and other hilly areas of the country. And the 19 national parks and 202 wildlife sanctuaries covering more than 2.3 per cent of the geographical area of India are inadequate to protect the many endangered habitats and threatened species, especially as most of the sanctuaries suffer from a lack of any scientific, or any other kind of effective management.

One of Indira Gandhi's first concerns when returned as Prime Minister after the election of January 1980 was to stem the degradation of the environment, and this led to the setting up of a fully-fledged government department to tackle the problems. The government is expected to announce far-reaching recommendations shortly, but for the time being there is a campaign to create awareness among the general public on environmental matters. This summer, for the first time, "environmental camps" are being held all over the country to involve young people in tree planting schemes, and to put a similar message over to the inhabitants of the rural areas where the camps will be based.

Sunil Saraf

CORRESPONDENCE

Non-academic staff

SIR — I was disturbed by your swipe at the "ancillary staffs" in your comment on cuts in the budget for London University (Nature 11 June, p.442). The planned reductions in staff, in such a short space of time, show little concern for the careers and livelihoods of individuals, but are also uneconomic. The average cost to the nation of each unemployed person is estimated at £5,000 per year in lost taxes and insurance contributions and unemployment benefit paid out. This excludes the loss of purchasing power, lost VAT income and lost productivity.

You wonder whether the universities' chief purpose is academic — but the universities create, directly and indirectly, wealth. Foreign students bring money into the country — this may now be lost to Canada, the United States and New Zealand. With that go many exports, both "visible" and "invisible" (such as the "influence" which the Foreign Office has always laid great store by).

The efficiency of universities is obviously affected by lack of equipment — and also by lack of staff. Academics in general earn more than the other staffs. If non-academic staffs are reduced in preference to academics, the tasks now performed by academics will become more expensive. Their teaching and/or research time will be eaten into.

Britain spends less on pre-school education per head than any of her competitors. Since the 1972 White Paper on education, the staff-student ratio in universities has increased by 10 per cent. During a recession one should be prepared for the recovery, otherwise recession will soon return. The cutbacks in education (and other areas) may permanently damage competitiveness.

M. HOOPER (University technician)

London N15, UK

The Tamuz raid

SIR — I do not object to the condemnation of Israel in your issue of 18 June ("Making Israel atone for Tamuz" p.523). On the contrary, I believe that articles such as these serve a useful purpose in that they strengthen and unify the world Jewish community. Moreover, condemnations are always preferable to condolences. It is remarkable, however, that a scientific journal such as *Nature* should tarnish its image by publishing an unscientific report that is replete with conjecture, ill-conceived logic, half truths and distortions.

To the question "Why should oil-rich Iraq be interested in nuclear power?", the scientific answer given by Nature is "Why not?". A long apologetic discourse follows rationalizing the presumed logic of creating civil nuclear technology in Iraq. How foolish! The Iraqi spokesmen themselves never bothered to contrive such a rationale for their reactor. President Hussein makes no bones about it — he wants bombs. He calls upon the world to "help Arabs acquire nuclear weapons — which are essential for world peace"; he also states that it is a "rational move for Arabs to try to acquire a bomb" — New York Times, 24 June, p.1.

The tears shed about the damage done to the "international reputation of the nuclear non-proliferation treaty" also amuse me. How

effective are the inspections? In the case of Iraq these were conducted on a limited basis, only by representatives of Communist bloc nations. Congressional testimony by Roger Richter, former American inspector of the IAEA (19 June 1981), shows how Iraq would have easily fooled reactor inspectors. Indeed, Iraq and some other nations are signatories of the treaty, but are we talking about responsible democratic societies? How much would it take for ruthless dictators, that suppress and murder political dissidents in their own countries, to abrogate an agreement? Perhaps it is time for the current ineffectual treaty to be replaced by a more meaningful one. We should all devote our efforts to promoting effective policies that would dictate limitation to the world arms race, and stop nuclear proliferation, rather than pontificate and lecture Israel about morality.

For the sake of future generations, the scientific community has the responsibility to do everything in its power to curb the real culprits in this case; the corrupt Western powers who are prepared to place nuclear energy at the disposal of madmen. In their hearts decent people thank the heroic Israelis for undertaking this necessary mission. Nuclear power must not be handed to demented killers.

IRVING LISTOWSKY Albert Einstein College of Medicine, New York, USA

Sir — Your editorial of 18 June (p.530) demonstrates clearly that *Nature* doesn't have offices in Israel. I take issue with your naive call for atonement on Israel's part for destroying Tamuz. Nations do not atone for legitimate acts of self-defence especially those committed during a declared war.

Egypt and Israel are at peace. The Egyptian nuclear programme is obviously needed for power production. For Iraq, peace with Israel is available for the asking. *Nature* should note that Iraq has been hostile to Israel since before Israel's independence. Iraq has not atoned for the mistreatment and expulsion of Iraqi citizens who happened to be Jewish.

It seems that you think that Israel should place its trust in the United Nations or the IAEA or the Big Powers or some other institution. Why? Did the UN stop the blockade of the straits of Tiran, did the United Kingdom and France obtain passage for Israeli shipping through the Suez Canal and when will Europe stop acquiescing in the Arab economic boycott of Israel? The credentials of world institutions do not call for trust.

Your editorial fails to mention the prospects for peace in the Middle East which were increased tremendously by the Israeli strike. It demonstrates that the cost of enmity to Israel is much higher than her enemies previously thought.

I realize that the cost to *Nature* of publishing a pro-Israeli editorial may be prohibitive in terms of lost advertising revenue and retaliatory terrorism but your respected journal should not dirty its image by ignoring history and simple logic to defend an attempt to destroy a nation.

PAUL ROTHBERG

State University of New York, Stony Brook, New York, USA

No badger vaccine

SIR — M.J. Chapman (Nature 28 May, p.278) commented on various aspects of the Zuckerman report on badgers, cattle and tuberculosis. It would be inappropriate for me to deal with the medical aspects to which Mr Chapman refers other than to note that my reading of these parts of the report differs from his.

I should, however, like to comment on the question of badger vaccination. The only vaccine for tuberculosis currently in use is made from a modified (attenuated) strain of Mycobacterium bovis and is used only in humans. In trials, the vaccine has given unpredictable results and is of no value at all as a treatment for infected cases. It has been tried in cattle and found to be neither effective nor practical. Its effect on badgers, whether healthy or tuberculous, is not known.

The mass vaccination of badgers seems to me, however, to be unpromising. While BCG vaccine can be given orally, very large doses are required compared with the amount given by intradermal injection. Oral application on the scale required seems quite impracticable. Furthermore, to be effective any vaccination of badgers would in all probability have to be carried out before they had been exposed to infection. Recent work has found that 13 out of 49 young cubs removed from setts in one of the problem areas were already infected. This suggests that vaccination would need to be done soon after birth which is, unfortunately, impracticable in the wild.

Mr Chapman asks for consideration to be given to the views of "many zoologists" who doubt the basis of ministry policy. I can assure him that we are in contact with many zoologists, both directly and through the minister's consultative panel, and that the ministry's own zoologists are closely involved in the work.

It is not my impression that there is a body of informed zoologists who differ fundamentally with the policy that we are following. In this connection I refer Mr Chapman to the statement issued earlier this year by the Nature Conservancy Council in which they endorse Lord Zuckerman's advice.

W.H.G. REES

Ministry of Agriculture, Fisheries and Food, Tolworth, UK

Elementary error

SIR — In Nature 16 April, p.538, in an article by Jasper Becker about accidents and problems at the French reprocessing plant at Cap de la Hague, mention is made of the hypothetical release of caesium-137 and rubidium-106 (if the cooling equipment for the radioactive waste storage reservoirs at La Hague had remained inoperative for ten hours).

Is the isotope number of rubidium perhaps in error, or the element? I do not find rubidium-106 listed in the CRC Handbook of Chemistry and Physics, 1980-81 edition.

A cycling index for ecosystems

fom Robert M. May

I have heard it said that the River Thames passes through two people on its way to the sea. While I am sure this is an extravagant exaggeration, such recycling is typical of the flow of nutrients in many ecosystems.

Finn¹⁻⁴ and others have presented a formal scheme for characterizing the patterns of flow of energy or nutrients through a complex ecosystem. In particular, Finn1 has shown how to compute a 'cycling index', which gives a quantitative measure of the extent to which flows recirculate within the system. This cycling index is the fraction of the total flow through the system that derives from cycling, expressed as a ratio to the fraction of the total that derives from flow straight through the system. Thus defined, the cycling index can clearly range from zero (no recycling anywhere in the system) to an arbitrarily large number (recycling overwhelming direct flow).

As derived by Finn and co-workers, these concepts apply to conservative systems at equilibrium, such that the books balance for overall inflows versus overall outflows. Finn observes, however, that the methodology may be extended to nonsteady systems. The actual meaning of the 'compartments' that make up the system can vary greatly (trophic levels, species, individuals); although this certainly bears on the interpretation of results, it makes essentially no difference to the formalism.

Finn has analysed the cycling of energy in several ecosystems^{1,2}. One example is part of a marine ecosystem (exhibiting marine coprophagy) and has four compartments5,6: the shrimp Callianassa major, the faeces of C. major and associated bacteria, coprophagous benthic fauna, and the faeces of the benthic fauna and associated bacteria. Here the cycling index, deriving from recycling between the third and fourth compartments, is 10.24. The second example describes energy flow in the Cone Spring ecosystem⁷, and has components for primary producers, detritus, bacteria associated with the detritus, detritus feeders and carnivores. Here the cycling index is 10.16. The third example draws on the extensive studies of the Hubbard Brook ecosystem8,9. Here there are essentially no energy loops, whence2 the cycling index is

Insofar as one can generalize from these three examples, it seems that energy can be recycled to a small but significant extent. Such recycling of energy is not in conflict with thermodynamic principles (energy, of course, cannot be degraded more than once), but arises because living systems can 'use' energy without degrading it. This is the case, for example, with the energy associated with structural or storage elements (such as cellulose, proteins or fats), which can either be catabolized or be used again as structural elements on transfer to the next compartment.

Finn² has also analysed the model of Likens and co-workers8 for the Hubbard Brook ecosystem, to estimate the patterns whereby various nutrients flow from the above-ground biomass through the belowground biomass and the forest floor to the mineral soil and the available nutrient pools. The cycling indices suggest significant differences in the degree of recycling, with the elements K, Na, N, Ca, P. Mg and S having indices around 0.83, 0.76, 0.76, 0.62, 0.60, 0.59 and 0.51, respectively. Finn² comments that "this order does not appear to relate to whether or not the system is gaining or losing a particular nutrient. Hubbard Brook is accumulating N, S, and P and losing Ca, Na, Mg, and K". Notice that the cations (K, Na, Ca, Mg) rank in strict order of atomic size and charge, which determines mobility (the so-called 'lyotropic series'). Of these seven elements, N and P are probably limiting, K, Ca, Mg and S are essential but nonlimiting, while Na is neither essential nor limiting (for plants). It is therefore a bit surprising that Na is recycled to such an extent at Hubbard Brook: Finn¹⁰ has shown that Na cycling indices can be very small, in other forest systems.

For Edmisten's11 model of a tropical rain forest, Finn1 finds the cycling index for N to be 1.78. This value, more than

double the 0.76 for N in the temperate Hubbard Brook forest, accords with the conventional wisdom about greater recycling of nutrients in tropical forests.

It is tempting to use Finn's cycling index in pursuit of other ecological generalities. We may, for example, expect to find that the cycling index typically increases as succession advances. Conversely, given that many kinds of pollution and other maninduced disturbances of mature ecosystems have effects akin to precipitating the system back into early successional patterns12, it may be that such perturbations are characterized by decreases in cycling indices. These are interesting speculations. They may even be taken to suggest that the cycling index could be a useful diagnostic in the design of environmental impact statements.

As Finn² himself has emphasized, however, "Flow measures do not take into account residence times or storages, but only the amounts of nutrients actually moving and the way in which they move. . . . all the different processes involved in nutrient cycling cannot be captured and quantified in a single index". The cycling index is an elegant construct, having both theoretical and practical significance; but when it comes to evaluating the impact of disturbances upon ecosystems, I would be wary of attempting to distill complex arrays of information about flow patterns into any such single number 13 .

Plasma lipoproteins and cellular metabolism

from J. S. Owen

PLASMA LIPOPROTEINS are macromolecular complexes in which lipids are bound to a variety of polypeptides (the apoproteins) through non-covalent forces. Four main classes of lipoprotein are recognized, each defined by the density at which it floats in the ultracentrifuge chylomicrons, very-low-density lipoprotein (VLDL), low-density lipoprotein (LDL) and high-density lipoprotein (HDL). Although these classes vary widely in size, and in lipid and apoprotein composition, they appear to have a similar general structure: they are spherical particles with a hydrophobic core of cholesteryl ester and triglyceride surrounded by a 2 nm-thick monolayer of apoprotein, cholesterol and phospholipid

Chylomicrons transport triglyceride and other fat-soluble substances from the intestine while VLDL transports endogenous triglyceride from the liver. The triglyceride contained in these particles is delivered to extrahepatic tissues, thereby providing cells with an important energy source. Although almost all cells can synthesize cholesterol, several clinical and biochemical studies suggest that most cellular cholesterol is derived from uptake and degradation of LDL. By contrast, one function of HDL may be to transport cholesterol from peripheral tissues to its principal site of catabolism and excretion in the liver.

These lipid transport processes are complex; they depend on an interchange of constituent lipids and apoproteins amongst the various lipoproteins, whether by exchange collision or by specific transfer proteins, and the activities of lipoprotein lipase, hepatic lipase and lecithincholesterol acyltransferase (LCAT). Other aspects of intravascular lipoprotein metabolism being investigated include the relationship between the various HDL subclasses and the mechanism by which specific HDL particles remove cellular cholesterol (Tall and Small Adv. Lipid Res. 17; 1, 1980), the origin of the lipoproteins producing cholesteryl ester deposition in the macrophage-like cells of the arterial wall (Goldstein et al. J. biol. Chem. 255; 1839, 1980, and Schechter et al. J. Lipid Res. 22; 63, 1981), and the involvement of the liver in LDL and HDL clearance (Pittman et al. Proc. natn. Acad. Sci. U.S.A. 76; 5345, 1979). In contrast, one aspect of lipoprotein metabolism has been relatively neglected: the influence of lipoproteins on cellular function by their regulation of selected cellular biochemical reactions and by their role in maintaining a normal cell membrane lipid composition.

The interaction of circulating hormones and certain non-hormonal molecules with

specific cell-surface membrane receptors is an important method of regulating cellular metabolism. Plasma lipoproteins also appear to possess this regulatory capacity. The elegant work of J. Goldstein and M. Brown at the University of Texas, Dallas has established that cultured cells have high-affinity receptor sites which recognize the apoprotein moiety (ApoB) of LDL. Subsequent studies, principally by R Mahley and colleagues at the National Heart and Blood Institute, Bethesda, have shown that ApoE-containing lipoproteins, including both HDL, (the HDL sub-class through which cholesterol may be delivered to the liver) and chylomicron remnants (the particles remaining after partial hydrolysis of core triglyceride), also bind to the same cell-surface receptor. After binding, these various lipoproteins regulate intracellular cholesterol metabolism and receptor activity, processes dependent on cellular uptake and degradation of lipoproteins.

Current evidence suggests that cells may also have additional lipoprotein receptors, specific for the apoprotein moieties and distinct from the classical 'LDL receptor'. and that lipoprotein occupancy of such receptors is sufficient to modulate selected cellular functions without requiring internalization of the intact particles. These include the activity of membranebound enzymes such as adipocyte adenylate cyclase and erythrocyte Mg2+-ATPase which are stimulated by VLDL and LDL, the enhancement of lipogenesis in fat cells by VLDL and the apparent LDL-induced reduction of prostacyclin production in endothelial cells. However, the type of regulation most extensively studied has been the potent inhibition of mitogen-induced lymphocyte proliferation by the ApoB- and ApoE-containing lipoproteins (Hui et al. J. biol. Chem. 255; 11755, 1980). J. Harmony and associates at Indiana University have shown that several primary mitogen-induced membrane events in lymphocyte transformation, such as calcium ion and cyclic GMP accumulation and phosphatidylinositol turnover, are markedly suppressed by membranereceptor binding of these apoproteins.

The membrane lipid composition of cells may be influenced by lipoprotein lipid composition as a consequence of the ready exchange between lipoprotein cholesterol and phospholipid (mainly phosphatidylcholine and sphingomyelin) and the corresponding lipids in cellular plasma membranes. Although cell membrane

transport, receptor and enzymatic functions are primarily determined by the protein constituents, there is considerable evidence that such membrane protein functions may be influenced by the properties of the fluid lipid bilayer matrix. A shift in the dynamic equilibrium between membrane and lipoprotein lipids, through abnormalities in lipoprotein lipid pattern, would therefore be expected to lead to changes in membrane lipid composition and so indirectly to membrane and cellular dysfunction. For example, the ratio of cholesterol to phospholipid is an important determinant of membrane fluidity, many membrane-bound enzymes depend on specific phospholipids for full activity, and phospholipid fatty acid composition may be a critical factor in secondary modulation of fluidity and in synthesis of prostaglandins.

Is there experimental evidence that this potential influence of plasma lipoproteins on cellular metabolism, through their effects on either membrane lipid composition or regulation of selected biochemical reactions, is physiologically important? Support has largely been obtained by study of those dyslipoproteinaemias, associated with either genetic, pathological, hormonal or dietary disturbances, in which substantial changes in apoprotein and lipid patterns have occurred. In this context, reports by N. McIntyre and his group at the Royal Free Hospital, London on the cellular abnormalities associated with the acquired LCAT deficiency of liver disease are of interest. Lipid changes were found in erythrocytes and platelets and the abonormalities correlated with cellular dysfunction (Owen et al. J. Lipid Res. 22: 423, 1981); there was also evidence in patients with liver disease that their abnormal HDL, enriched in ApoE, could effect cellular regulation by reducing LDL uptake, by altering erythrocyte morphology and by suppressing lymphocyte proliferation. However, the majority of cells studied in such cases of abnormal lipoprotein composition have been isolated from the lipoprotein-rich environment of the plasma compartment and clearly there is a need to extend these observations to cells which have access only to the lipoproteins of the extravascular fluid. That such investigations will be fruitful is suggested by the interactions of abnormal lipoproteins with cultured cells and by the poorly understood metabolic and cellular disturbances frequently associated with those dyslipoproteinaemias, such as primary and secondary LCAT deficiency and abetalipoproteinaemia, in which marked changes in lipid and apoprotein composition occur.

MST radars: advanced tools for gravity wave studies

from Jürgen Klostermeyer

In 1974, Woodman and Guillén1 published observations of winds, gravity waves and turbulence in the neutral atmosphere obtained by the powerful Jicamarca radar in Peru. The radar operates in the very high frequency (VHF) band at a frequency of 50 MHz (wavelength = 6 m) and was originally built for investigations in ionospheric heights. Their work stimulated the construction of several VHF Doppler radars which were specifically designed for studies in the mesosphere, stratosphere and troposphere²⁻⁴ (MST radars). Their ability to measure simultaneously height profiles of background winds, atmospheric gravity waves and turbulence makes them unique instruments for studying not only each process separately but also their nonlinear interactions.

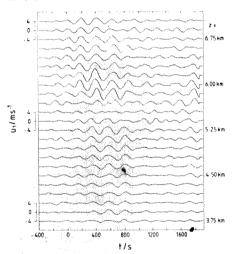

Fig. 1. Line-of-sight velocity oscillations at heights between 3.75 and 7.05 km produced by a Kelvin — Helmholtz instability during a jet stream passage. Sliding scales on the left indicate velocity amplitudes up to 3 m s⁻¹. Parameters on the right denote the heights at which the velocities were measured. The measurements were made by the German SOUSY MST radar with height and time resolutions of 150 m and 10 s. (From Klostermeyer and Rüster¹⁴.)

The radar echoes are produced by both scattering from refractive index structures with scales equal to half the radar wavelength and partial reflections from refractive index gradients. Refractive index variations are due to changes in temperature, pressure, humidity and concentration of free electrons. Humidity changes are most important in the troposphere whereas free electrons play a major part only during daylight hours at mesospheric heights above some 50 km. In the troposphere and stratosphere, the radar echo power decreases strongly with height due to the exponential decrease of

the air density whereas in the mesosphere, the free electrons give rise to a small local power maximum. The small radar scattering cross-section of the turbulent fluctuations requires extremely sensitive radars with operating frequencies preferably below 50 MHz⁵. However, depending on daytime and mode of radar operation, there is always a more or less extended height range around the stratopause refusing the onslaughts of even the most potent MST radars.

MST radars are phase coherent so that transmitted and received signals can be compared to get both amplitude and phase of the signals returned from any height. The usual procedure is to find the echo power density as a function of the Doppler shift from the transmitter frequency. This Doppler spectrum contains the necessary information about the intensity of turbulent refractive index fluctuations at scales equal to half the radar wavelength, the mean velocity of the scattering volume in the direction of the antenna beam (lineof-sight velocity) and the distribution of random velocities within the scattering volume1. The total velocity vector can be obtained by changing the direction of the antenna beam. The temporal and spatial resolutions depend primarily on the signalto-noise ratio of the radar echoes, optimum resolutions are a few seconds and a few tens of metreo6.

Due to their excellent range and time resolutions, MST radars offer unique opportunities for studying the role of gravity waves in various atmospheric processes. Radar records show that gravity waves with periods between a few minutes and several tens of minutes are generally present at all heights below 100 km. At Jicamarca, several experiments using two or three antenna pointing directions were performed to measure both wave periods and horizontal and vertical phase velocities⁷⁻⁹. The results show dominant periods of between 5 and 10 min, the range of the Väisälä-Brunt resonance period in the atmosphere below 100 km. The majority of the waves propagates horizontally indicating that there is no vertical energy transport. This suggests wave sources within the observed height range rather than sources far below or above it.

A few radar experiments indicate that there are height levels at which the horizontal phase speed of observed gravity waves matches the wind speed. A wave encountering such a 'critical' level

Jürgen Klostermeyer is at the Max-Planck-Institut für Aeronomie, Germany. transfers momentum and energy to the wind or vice versa depending on the strength of the vertical wind shear. In the presence of strong wind shears, a gravity wave reflected from a critical level may be stronger than the incident one. Within the

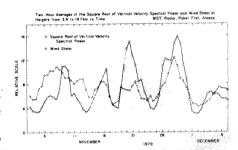

Fig. 2. Time variation of square root of gravity wave spectral power and vertical wind shear. The gravity wave spectrum was obtained by the Poker Flat MST radar in Alaska with height and time resolutions of 2.25 km and 1.5 min in the height range from 4 to 20 km. The wind shear data were derived from radiosonde ascents at Fiarbanks, Alaska. (From Ecklund et al. 15.)

limits of available information, this process of 'over-reflection' could be observed by the Jicamarca radar 10. Another process closely related to overreflection is the Kelvin-Helmholtz (K-H) instability: in regions of strong wind shear, small perturbations in the meteorological noise may grow exponentially with time and rise far above the initial noise level. The horizontal phase velocity of the resulting wave matches the wind speed somewhere within the shear region so that there is again a critical level providing energy transfer from the wind to the wave. In the upper troposphere, polar front jet streams have strong shears and thus act as gravity wave sources via the K-H mechanism11-13. Oscillations of the line-ofsight velocity at several heights which were generated by the K-H mechanism at the bottom side of a jet stream are shown in Fig 1. The amplitude varies strongly with height and has two maxima near 5 and 6 km, whereas the phase is almost constant in the lower and upper regions. The critical level is at 5.55 km and is characterized by a marked amplitude minimum and a rapid phase change with height.

Gravity waves have horizontal wavelengths from a few kilometres up to a few 100 km and thus cannot be resolved on the grid scales of forecasting and general circulation models. Since they play an essential part in the redistribution of momentum and energy from large-scale to small-scale atmospheric motions, proper methods have to be developed to parameterize their effects in terms of large-

scale motions. This task requires, among other things, research on the synoptic variability of gravity waves. An important step in this direction has recently been taken by Ecklund et al. 15 who used part of the yet unfinished Poker Flat MST radar in Alaska to demonstrate that gravity wave activity is strongly controlled by propagating planetary waves. Whenever intense baroclinic zones moved across the radar site, the power of the gravity wave spectrum at tropospheric heights increased significantly. Intense baroclinic zones in turn are associated with strong winds and wind shears pointing towards K-H instability as a major source mechanism. Figure 2 shows the variation of the square root of the gravity wave spectral power along with the mean vertical wind shear for a period of 34 days indicating a good correlation between both quantities. This strongly suggests that K-H instabilities affect the life expectation of synoptic disturbances by continuously borrowing from their energy and momentum budgets.

Future applications of MST radars will

be directed towards more intensive studies of sources and sinks of gravity waves and their interaction with large-scale and smallscale atmospheric motions. Preliminary investigations during thunderstorms indicate, for example, that fast-rising air parcels in cumulus clouds can penetrate through the tropopause into the convectively stable stratosphere, thereby exciting a broad spectrum of gravity waves¹³. At heights below 100 km, genesis of turbulence is probably the most important wave sink besides absorption at critical levels. Radar observations show that strong bursts of turbulence arise

whenever a gravity wave generates convectively unstable regions¹⁴. Such bursts are probably identical with clear air turbulence that occasionally threatens aircrafts. In considering the stability of gravity waves we arrive at the problem of parametric instabilities. Waves with finite amplitudes so small that shear or convective instabilities do not occur should enhance a spectrum of disturbance waves by their rocking motions (like the excitation of a swing by a child). This is one of a variety of nonlinear gravity wave processes awaiting their discovery by MST radar experiments.

X-ray laser obtained by pumping with a nuclear bomb?

from Peter Knight

RUMOURS have been buzzing around the laser community for some months that an X-ray laser has been made to work by a group led by George Chapline of Lawrence Livermore National Laboratory, Initial reports in the February 23 issue of Aviation Week and Space Technology (stressing military applications) have been followed by notes in the April and May issues of Laser Focus that the Livermore group tested a device pumped by a small nuclear bomb at the DoE Nevada Test Site and produced a pulse of several hundred terawatts of X rays at 1.4 nanometres. So far no official comment or confirmation has been made by the Livermore. As the correspondent of Laser Focus points out, 1.4 nanometres corresponds to the Ka line of neon. Early reports that nanosecond pulses were produced seem unlikely since such a device would probably operate as a singlepass self-terminating amplified spontaneous emission system limited at least by the picosecond upper state lifetimes. Picosecond or femtosecond pulse lengths would be more reasonable. The rumoured experiment has attracted much interest and a full account is eagerly awaited. Past efforts in this field have not survived careful scrutiny. Since a nuclear bomb is necessary in the present case, it seems difficult to check by independent experiment.

It is very difficult to create the right conditions for X-ray laser action. No mirrors are envisaged and single-pass gain

must be high enough that spontaneous fluorescence is efficiently amplified by stimulated emission during its transit down a rod-shaped inverted medium. A gain of about 100 dB is required according to G. Chapline and L. Wood (Physics Today June 1975, p.40) and this requires inversion densities $N^* > (\Delta \nu / L) \times 10^{18} \text{cm}^{-3}$ where $\Delta \nu$ is the bandwidth in electron volts and L is the length of the inverted medium in centimetres. 'Cold matter' has an Auger bandwidth $\Delta \nu \sim 1$ eV and enormous pump intensities are required to reach such large values of N^* . In a plasma, Δv is governed by Stark widths and then $N^* > 5 \times 10^{19}/L$ cm⁻³ which requires fractional inversion $N^*/N \simeq 10^{-3}$. If pump intensities are such that $N^*/N < 10^{-3}$, then one way out is to use material of more than solid density obtained through some compression scheme. It is interesting to note in this context that the Livermore experiment was supposed to be pumped by a nuclear bomb.

Many schemes for producing X-ray population inversion have been studied. Most use very high-power laser excitation of plasma targets. Promising results using this route have been reported by workers at the University of Hull (D. Jacoby et al. Opt. Commun. 37; 193, 1981) with the Balmer α line of Carbon VI at 182Å. An early proposal due to M. Duguay and P.

Peter Knight is in the Optics Section of the Blackett Laboratory, Imperial College, London,

Rentzepis (Appl. Phys. Lett. 10; 350, 1967) suggested exploiting the frequency dependence of photoionization crosssections to produce inversion. Tightly bound electrons are actually more easily photoionized by X rays than weakly bound electrons, so that an incident high-intensity flash of X rays could produce population inversion by leaving ions in excited states. Conventional X-ray sources are not bright enough to achieve the required gain. It is possible that nuclear explosions can produce the required rapid inversion and one might guess that this was used in the Livermore experiment.

The properties of coherent X-ray sources are so valuable that great efforts are being made to construct a useful X-ray laser device. If one were available, phasecontrast microscopy would make atomicscale resolution of the dynamics of biological systems in situ possible, could solve the phase problem in X-ray crystallography and lead to the study of atomic dvnamics with $\sim 10^{-15}$ second resolution. The nuclear bomb-pumped single-shot X-ray laser would be of value in scientific diagnostics but would not seem to be a route to a useful device. Nevertheless, it does represent an invigorating advance which might help in obtaining funds to continue the expensive investigation of potential X-ray laser systems. We will have to wait for more details than the leaked rumours before a proper assessment can be made.

More surprises from mitochondria

from Thomas D. Fox

MITOCHONDRIAL GENETICS began in the 1940s with the work of Boris Ephrussi on cytoplasmic petite mutants in yeast (Saccharomyces cerevisiae); these petites (which have extensive deletions of mitochondrial (mt)DNA) still figured in many reports at a recent Cold Spring Harbor meeting on 'Mitochondrial Genes' held in his memory. However, the study of mitochondrial genes, with or without genetics, has now been extended to a wide range of organisms. Some patterns are beginning to emerge from the comparisons, and some are not. To sum up, one might say that the functional proteins produced by mitochondrial genetic systems are generally highly conserved, while the structure, coding and modes of expression of the genes that specify them are astonishingly different in the various major groups of eukaryotic species.

Although yeast has long been the favourite organism for mitochondrial genetic studies, the best characterized mitochondrial genomes are now those of mammals. The complete human and bovine mtDNA sequences (S. Anderson, MRC Cambridge) and an analysis of transcripts from the human organelle (G. Attardi, California Institute of Technology) were reviewed. These studies and a comment on them recently appeared in Nature 290, April 9, 1981 and little new was left to report at the meeting. In brief, these geonomes are highly compact, containing virtually no intergenic DNA and no intervening sequences within genes. Discrete transcripts appear to be cut from long precursors, generally at sites 'marked' by tRNAs, and have little or no untranslated sequence at either end. There is probably only a single promoter for transcription of each strand. The genome codes for five proteins of known function and up to eight unknown proteins appear to be coded by unidentified reading frames, or URFs. The identity and function of the URF polypeptides remains one of the major unanswered questions in this system.

A comparison of the genomes of yeast and mammals reveals very little similarity except for the deduced amino acid sequences of the five identified proteins. The yeast genome is anything but compact, with large A+T-rich regions between genes. Unlike the orderly process of mtDNA replication in animals, involving well defined start and even stop signals (D. Clayton, California Institute of Technology), there appear to be multiple origins of replication for yeast mtDNA (G. Bernardi, University of Paris; H. Blanc, Stanford University). Duplication of these origins may have helped generate the

A+T-rich DNA since Bernardi finds that origin-like sequences occur in these regions more often than expected randomly. Like replication, transcription is also more complex in yeast than in mammals, involving not only processing but multiple promoters as well. Independent primary transcripts, retaining di- or tri-phosphate 5' ends, can be detected for the regions coding the large and small rRNAs, and from at least four other sites around the genome (D. Levens, University of Chicago).

A yeast mitochondrial gene required for the synthesis of mitochondrial tRNAs has been identified and mapped (N.C. Martin, University of Texas, Dallas). The gene product is unknown, but is active in petites (which lack mitochondrial protein synthesis) and thus cannot be a protein. A plausible hypothesis here is that a mitochondrially coded RNA interacts with a cytoplasmically made protein, imported into the mitochondria, to form an enzyme (similar to RNaseP of E. coli) that processes mitochondrial tRNA precursors. A converse problem, that of a gene product in search of a gene, also arises in yeast, namely, where is the gene for the var-1 polypeptide (see Nature 289; 119, 1981)? Although mitochondrially inherited genetic determinants cause polymorphic variations in this mitochondrially synthesized ribosomal protein, no structural gene can be found in yeast mtDNA (R.A. Butow, University of Texas, Dallas).

Several yeast mitochondrial genes contain introns, and intron-2 of the cytochrome b gene (cob) appears to code for a protein, termed maturase, which is required to splice out the intron itself (see Nature 289; 439, 1981). Studies on intron-4 of cob have revealed a similar, but rather more complex picture. First, mutations in this intron can block the processing not only of cob transcripts, but also those of the mitochondrial gene coding cytochrome oxidase subunit I. Second, several new polypeptides appear in intron-4 mutants. although only one seems to be directly affected by a mutation in the open reading frame (H. Mahler, Indiana University). Finally, there are cis-dominant mutations both in the intron's open reading frame and in the non-translatable region preceding the next exon (C. Jacq, CNRS Gif). However, one can avoid dealing with these complications if one simply makes them disappear. P. Pajot (CNRS Gif) has

Thomas D. Fox is at the Biocenter, Basel, Switzerland, but will be moving shortly to the Section of Genetics and Development, Cornell University. done just that by isolating a spontaneous mutant in which *cob* introns 4 and 5 were both deleted, but which still made functional cytochrome b. This indicates that both introns were very precisely excised; where they went is unknown. Furthermore, owing to a nuclear mutation that occurred simultaneously with the intron deletions, cytochrome oxidase subunit I is made despite the absence of *cob* intron-4!

Two features of the Aspergillus nidulans mitochondrial genome are particularly revealing when compared with those of yeast and mammals (R.W. Davies, University of Essex). First, the cytochrome b gene of Aspergillus has a single intron, whose position corresponds almost exactly to intron-3 of the yeast cob gene, and whose anatomy closely resembles that of the 'maturase-coding' intron-2 of cob: it has an open reading frame in register with the preceding exon, followed by a short untranslatable region. Thus mitochondrial intron splicing mechanisms may be conserved, at least in fungi. Of even more interest to humans is the fact that Aspergillus mtDNA has two open reading frames which would code for proteins homologous to the URF-1 and URF-4 proteins coded by the mammalian genome. This finding indicates that these polypeptides are conserved beyond the animal kingdom, and raises the possibility of examining their function by genetic analysis in fungi. It also begs the question, where are these genes in yeast? Extensive sequence studies in yeast by A. Tzagoloff and co-workers (Columbia University) have not located them, and the prospects of doing so appear bleak. Are they in the yeast nucleus?

That genes have moved between the mitochondria and the nucleus is well established by the case of the ATPase subunit 9 gene, which is mitochondrial in yeast but nuclear in Neurospora crassa (see Tzagoloff et al. A. Rev. Biochem. 48; 419, 1979). Tha tmoving genes may leave tracks has now been demonstrated by the finding that the Neurospora mitochondrial genome nevertheless contains what appears to be a pseudo-gene for ATPase subunit 9: a homologous sequence with an in-frame stop codon and a region of gibberish in the middle (van den Boogaart, State University, Groningen).

The mitochondria of higher plants have large genomes (greater than 100 kilobases), synthesize more proteins than their fungal counterparts, and in some cases also contain linear plasmid molecules whose presence is associated with cytoplasmically inherited male sterility of the plants. Detailed analysis of plant mtDNA will be

accelerated by the fact that defined probes for yeast genes can be used to pick out homologous sequences by crosshybridization (C.J. Leaver, University of Edinburgh). Protozoan parasites, yet more distant relatives of yeast, must also have homologous mitochondrial genes because yeast mtDNA coding for three cytochrome oxidase subunits and for cytochrome b gave specific signals when hybridized at low stringency to fragments of the kinetoplast maxicircle DNA from Leishmania tarantolae (L. Simpson, University of California, Los Angeles).

One aspect of genetic systems that is not supposed to evolve, the genetic code, apparently does so in mitochondria. Several differences exist between the codes used in mitochondrial genes of mammals and yeast (see Nature 287; 9, 1980). The only feature common to them (and to Neurospora and Aspergillus) but not to nuclear genes is the coding of tryptophan by UGA. However, it now appears that the use of UGA for tryptophan may not even be 'universal' for mitochondria, as the gene coding maize cytochrome oxidase subunit II does not contain UGA codons (T.D. Fox, Biocenter, Basel). Instead, the maize gene appears to use the codon CGG for tryptophan, in addition to the standard UGG.

Another established coding novelty in mitochondria is the ability of a number of single tRNA species with U in the wobble position to read all four codons in a family (Nature 287; 9, 1980). Several tRNAs, however, whose gene sequence predicts U at the wobble position, read only codons ending in A or G. In Neurospora, this dilemma is apparently resolved by a modification of the U in those tRNAs with restricted pairing (Heckman et al. Proc. natn. Acad. Sci. U.S.A. 77; 3159, 1980). While similar modified U residues have now been found in the corresponding tRNAs of yeast (R.P. Martin, CNRS Strasbourg), the mammalian systems must use another method to restrict pairing as direct tRNA sequencing has revealed no modified U residues at the wobble position of mammalian mitochondrial tRNAs (S. Anderson, MRC Cambridge).

Not only the evolution of mitochondria themselves was discussed at the meeting, but also the use of mitochondrial studies to trace the evolution of the organisms in which they reside. Since the evolutionary rate of base pair substitutions in the mtDNA of vertebrates is approximately ten times that in nuclear DNA (Brown et al. Proc. natn. Acad. Sci. U.S.A. 76; 1967, 1979), mtDNA provides a unique highresolution tool for examining relationships among animals whose divergence times are relatively short. For example, a comparison of the DNA sequences of homologous regions of mtDNA from humans and four great apes allows the derivation of an evolutionary tree more firmly rooted in data (over 300 base pair substitutions) than has hitherto been

possible (W.M. Brown, University of Michigan). Studies of mtDNA restriction map polymorphisms within our own species indicate that *Homo sapiens* probably arose from a small group of individuals as recently as 130,000 years ago, although an anomalous restriction pattern from a single individual has led to speculation that 'non-sapiens' mitochondrial genomes could still be present in modern human populations (R.L. Cann, University of California, Berkeley).

Somewhat lost in the discussion of mitochondrial genes was the fact that their

expression must be largely under the control of nuclear genes. This point was brought home forcefully by the description of several nuclear mutants of *Neurospora* which fail to splice the intron from the large mitochondrial rRNA precursor (A.M. Lambowitz, St Louis University), and a nuclear mutant of yeast that specifically lacks any detectable transcripts of the *cob* gene (C. Dieckmann, Columbia University). Much more activity in this area can be expected in the future, and the fungi will again probably lead the way — at least until the complete sequence of the human nuclear genome becomes available.

A golden age of astronomy

from Ben Zuckerman

THE latter half of the 20th century is one of the two golden ages of astronomy. This has primarily been a result of the opening up of new wave bands that extend over the entire electromagnetic spectrum. Excitement should continue with major technological advances anticipated in construction of new telescopes with larger collecting areas and improved spatial resolutions. The latter was emphasized at a meeting* entitled the "Scientific Importance of High Angular Resolution at Infrared and Optical Wavelengths".

The fundamental problem in achieving high angular resolution with ground-based telescopes is, of course, posed by the atmosphere of the Earth which distorts and distends the diffraction-limited images of all large telescopes at visual and nearinfrared wavelengths. Currently, there are three main techniques for achieving high angular resolution. A. Labeyrie (Centre d'Etudes et de Recherches Géodynamiques et Astronomiques) reviewed the field of speckle interferometry. The application of this technique to optical and infrared astronomy has been pioneered by himself and his French colleagues. C. H. Townes (University of California, Berkeley) multiple telescope discussed interferometry in the infrared emphasizing the heterodyne technique that he and his research group have developed. The third technique. Michelson interferometry, has been utilized, in the optical, by D. Currie (University of Maryland) and, in the infrared, by D. McCarthy, R. Howell and F. Low (University of Arizona).

The best angular resolutions achieved to date are due to the CERGA group who have been operating a 35-m baseline interferometer in southern France and observing fringes with a photon-counting TV camera which integrates every 20 milliseconds. This system has measured stellar angular diameters and binary star

separations as small as 1 milli-arcsecond. A new 350-m baseline optical interferometer with novel concrete support structures for damping flexures may be operating at CERGA within a year's time. Baseline flexures at a level of only a few microns can obliterate the fringes. Because of phase jitter due to the atmosphere, the faintest object measureable with such an interferometer is about 10⁵ times brighter than could be studied with a space interferometer of equal size. D. Dravins (Lund Observatory) described a proposed ground-based optical interferometer that would have substantially longer baselines - up to 100 km - capable, in principle at least, of achieving micro-arcsecond resolution. This would be a digital version of Hanbury Brown's intensity interferometer which has successfully measured angular diameters of bright, hot stars at the milli-arcsecond level. Here the signals from separate telescopes are mixed after detection rather than before as in all the other techniques mentioned above.

Speckle interferometry attempts to compensate for distortions due to atmospheric fluctuations by very short exposures that 'freeze' the image in a time interval that is shorter than the characteristic time scale of these fluctuations. An alternative approach to that of speckle interferometry is active optics. J.W. Hardy (ITEK) described how the figure of the primary or secondary mirror is actively controlled on a time scale that matches atmospheric changes and, also, distortions in the telescope figure induced by variations in gravity or temperature. J. E. Nelson (University of California, Berkeley) described a University of California design for a 10-m diameter segmented hexagonal primary mirror. The 36 segments, each 1.8-m in diameter, would be controlled by 168 displacement sensors, 3 tilt sensors and 108

^{*}The meeting was held at the new headquarters of the European Southern Observatory in Munich from March 24 to 27.

displacement actuators. Townes pointed out that modern telescopes are already so complicated that these actuators do not represent a great increase in complexity.

Among the highlights of the meeting were discussions of unusual galaxies such as quasars and Seyferts by M. J. Rees (University of Cambridge) and by the chair-person of the scientific organizing committee, M. H. Ulrich (European Southern Observatory). Rees considered how measurements of the shape, location and fine structure of a quasar imaged by a foreground gravitational lens could be used to deduce the distribution of mass in the lens. In the most likely case where the lens is a massive galaxy, angular fine structure in the quasar image on a scale ranging from one arc second down to one micro-arcsecond could be used to distinguish mass contributions in the lens that range between entire galaxies and single stars. Since there is, at present, roughly 70 orders of magnitude uncertainty in the mass of the paramount contributor to the unseen mass in galaxies (ranging all the way from massive neutrinos to million solar mass black holes), such measurements are of considerable interest.

Finally, there was discussion of the future of large telescopes and, specifically, whether large single apertures (up to 10- or 15-m diameter) are preferable to somewhat smaller telescopes operating as an interferometer. As might be expected, no consensus was achieved. R. Angel (University of Arizona) lamented that the Multiple Mirror Telescope on Mt Hopkins in Arizona is the first real technological innovation in 50 years in optical astronomy. But it seems clear, from the impressive results already achieved by the CERGA group and others and by the range of novel proposals presented at the conference, that high angular resolution ground-based and space-based optical and infrared astronomy has a bright future.

From embryo to teratocarcinoma in tissue culture

from Brigid Hogan

Mouse teratocarcinomas are well established as a versatile model system for the study of gene expression and cell interaction during early mammalian embryogenesis. In culture, aggregates of the pluripotent stem cells, known as embryonal carcinoma (EC) cells, differentiate into embryoid bodies resembling the inner cell mass of the early mouse embryo. At first, these structures consist simply of an outer layer of endoderm surrounding a solid core of epiblast (or primitive ectoderm) cells, but many subsequently develop a quite complex organization, with various tissues derived from endoderm, ectoderm and mesoderm. However, the most dramatic evidence for the ability of EC cells to differentiate in an orderly and coherent sequence is undoubtedly their behaviour when injected into normal mouse blastocysts. Here, the cells integrate with the host inner cell mass and in the course of development may contribute towards most tissues of the chimaeric offspring.

Impressive as these results are, the degree of chimaerism obtained after injecting EC cells is unpredictable, to say the least. With some cell lines, the probability of an EC cell differentiating into normal tissues is very low, and cells which fail to do so may give rise to tumours. With other cell lines, the frequency and extent of chimaerism is much higher, although still unpredictable, and only in few tissues is the contribution more than 50 per cent. One of the most

Brigid Hogan is in the Mammalian Development Laboratory, Imperial Cancer Research Fund Laboratories, Mill Hill, London. celebrated chimaeras was "Terry Tom", a mouse in which nearly all tissues, including sperm, were populated by derivatives of EC cells of the OTT 6050 line, which had been maintained in the laboratory for more than 8 years as an ascites tumour 1.2. The prospect of generating more mice like Terry Tom, carrying germ cells derived not only from standard EC lines but also from teratocarcinoma cells selected *in vitro* to carry specific mutations, or new DNA sequences, ideally inserted into specific chromosomes, has inspired an immense amount of effort

One of the ultimate goals of this work is to engineer strains of mutant mice which can act as models for human genetic diseases3, so male mice, which can transmit chromosomes to large numbers of offspring, are particularly prized. But, in spite of the fact that EC cells carrying specific nuclear or mitochondial mutations4, human5 or rat6 chromosomes, or foreign DNA6 have been generated and in some cases injected into blastocysts and incorporated into chimaeric offspring, the colonization of the male germ line remains elusive. One reason for this is undoubtedly the fact that all the established EC lines so far used for genetic manipulation have an XO karyotype — that is, they have lost the Y chromosome during prolonged culture. For this reason, it would be very useful to be able quickly grow new teratocarcinoma cell lines from normal male embryos, insert genetic material or mutations into them, and make chimeras, either by blastocyst injection or by the simpler technique of aggregation with monula-stage embryos7. Recent successes with nuclear transplantation in mouse eggs8 may

100 years ago

STUDENTS of Cretaceous geology will regret to hear that Griffiths, the well-known "fossil man" of Folkestone, has been disabled for many months by rheumatism, brought on by constant exposure during the past twenty-five years, in which he has daily extracted from the wet and slippery tract of Gault clay in Eastweir Bay the remarkable series of mollusca with their pearly nacre preserved, plants, corals, crustacea, and reptilian remains that ornament not only the private collection of those who make the Gault a subject of special study, but the national museums both of this country and of the New World. In addition to collecting by far the most perfect specimens of the

Gault fauna and flora hitherto obtained, Griffiths has rendered an important service to science in carefully noting the bed or horizon from which each specimen was procured, which identification has formed the groundwork of the divisions which English geologists have been able to make in the Gault, and the correlation of these zones by M. Barrois and others with deposits occurring on the Continent. In consideration of these results, carried out by a working man under the difficulties of a struggle for life with circumstances, and the rigorous weather of the English Channel coast, it has been thought advisable to appeal to English geologists to raise a small fund which should render it unnecessary for work to be carried on when dangerous to health, and to tide him over present difficulties.

The evening *fête* of the Royal Horticultural Society was held on the 28th ult. in the Gardens at South Kensington. Coloured

lamps were disposed about the lawn, and here and there the cool plash of fountains was to be heard. The Siemens and Maxim electric lights were placed in the upper part of the Gardens, and in the lower part were two tents illuminated by the Brush electric light, and containing the plants of a flower-show, which continued next day. Brilliant effects were obtained with coloured fixes behind the trees and the spray of the fountains.

There was recently landed at Marseilles a magnificent zebra which the King of Choa, Menelick II, has sent as a present to the President of the French Republic. This zebra, called the Semephore, has been brought from Abyssinia by two Marseillais. The Société de Géographie, to which it was addressed from Aden, has intrusted it to the Marseilles Zoological Garden.

From Nature 24, 224-226. July 7, 1881.

eventually make it possible to obtain mice in which all the genetic information comes from one teratocarcinoma nucleus.

Until now, however, isolation of new teratocarcinoma cell lines has been a lengthy procedure involving transplantation of genital ridges or early embryos into extra-uterine sites such as the kidney or testis. In this environment pluripotent cells in the graft continue to grow and may give rise to tumours containing populations of EC cells which can be maintained during serial transplantation and then tissue culture. These techniques restrict work to inbred strains of mice since, for unknown reasons, tumours containing EC cells fail to develop from grafts into nude or immunosuppressed animals9.

Over the years, many attempts have been made to circumvent these restrictions by generating EC cell lines from embryos cultured in vitro. Now, Martin Evans and Mat Kaufman in Cambridge have at last been succesful (see this issue of Nature p.154). Studies in several laboratories suggest that EC cells have more biochemical properties in common with epiblast cells in the inner cell mass of 51/2-day blastocysts around the time of implantation, than with pluripotent cells present earlier or later. Normally, the number of epiblast cells is small but this increases when implantation is delayed by treating the mother with hormones. Evans and Kaufman collected batches of delayedimplantation blastocysts, allowed them to attach and spread in vitro, harvested the embryonic knobs containing the epiblast cells, dissociated them in trypsin and plated the cells on a feeder layer of non-dividing fibroblasts. After a few days clumps of EClike cells were located, dissociated and reseeded, and several cycles of such treatment yielded cultures containing predominantly undifferentiated EC cells.

The trick seems to be to provide conditions in which the pluripotent cells in the embryos are both encouraged to proliferate, either in response to growth factors made by themselves or the feeder fibroblasts, and discouraged from differentiation by disrupting cell-cell interactions. Using this technique Evans and Kaufman have isolated at least 15 new pluripotent teratocarcinoma cell lines. some from outbred mouse stocks. Those which have been analysed have a completely normal karvotype, including two with an XY genotype. It remains to be seen whether these new teratocarcinoma lines are particularly efficient at colonizing normal embryos and, in particular, the male germ line. Meanwhile, the technique opens up many exciting possibilities for exploiting the teratocarcinoma system more fully. For example, EC cells could be isolated from mouse strains carrying electrophoretic variants of X-linked enzymes, or from T/t mutants blocked in postimplantation development, and the biochemical properties of these cells followed during the in vitro development of mass cultures as embryoid bodies.

One criterion used by Evans and Kaufman to identify their teratocarcinoma stem cells is expression of a specific, cellsurface carbohydrate sequence recognized by one of the monoclonal antibodies made in humans suffering from a rare haemolytic

disease known as 'cold agglutinin disease'. These people make antibodies against different, chemically defined, carbohyrate domains of the Ii blood group antigens. The antibodies have been used by Ten Feizi and her colleagues at the Clinical Research Centre in London and Martin Evans in Cambridge as highly specific probes with which to follow the transient expression of carbohydrate sequences on the surface of different cell population during early mouse development¹⁰. These studies have now been extended by Gooi and the above workers (see this issue of Nature p.156) to define the carbohydrate sequence reconized by a monoclonal antibody SSEA-1 raised in mice immunized with teratocarcinoma EC cells11 and to show that simple glycosylation steps involving addition of branch points or extra fucose or sialic acid groups occur at different stages of development. The significance of these subtle changes in terms of cell interactions, binding of hormones and growth factors, or morphogenesis remains to be seen.

The ultimate computer

from Paul Davies

BLACK HOLES, it seems, get into everything these days. Jacob Bekenstein who, along with Stephen Hawking. invented quantum black holes, turns his attention to the more practical issue of telegraphy in a recent paper (Phys. Rev. Lett. 46; 623, 1981). In the spirit of Shannon's celebrated analysis of the limits on information transfer through a communication channel, Bekenstein deploys some remarkable arguments gleaned from his experience with more astronomical matters.

The basis of this new departure is an unexpected relation, recently published by Bekenstein himself, connecting the ratio of entropy to energy for any physical system, with its physical size. The ratio is bounded by the dimension of the system, whether it be a black hole (an extreme case) or a box of photons. Using the fact that information is the negative of entropy, Bekenstein turns his new relation inside out to address the problem of energy limitations on information

The transmission of information is expensive, as every telephone subscriber knows. The pressing question is whether the energy dissipation can, in principle, be arbitrarily reduced by some future technological innovations. Bekenstein says no, even if you try to get the theory of relativity to help. His result is disarmingly

information rate = $(2\pi^2/h \ln 2) \times \text{energy}$ where h is Planck's constant.

Turning to an obvious application, Bekenstein considers the maximum conceivable speed of a digital computer. These days computers are so fast that designers have to worry about the speed of light being a limiting factor. We are already in the era of the relativistic computer. To beat the speed of light one can try to make the device smaller, but then quantum theory threatens. Ultimately an over-compact computer risks imploding under gravity down its own black hole.

In a somewhat rule-of-thumb analysis Bekenstein considers the problem of computer overheating. There is an inevitable entropy generation involved in shunting any information around, and in the end this will melt the system unless it is efficiently cooled. The author considers various cooling mechanisms and their inherent limitations, and eventually comes up with the best performance criterion for the ideal computer: 1015 operations per second.

That is pretty fast by contemporary standards, so Bekenstein's limit will not cause too many sleepless nights in the computer industry just yet. Nevertheless, an ultimate bound on any form of technology is intriguing in its own right, and it would be interesting to see whether the idea is followed up.

Tempo and mode in hominid evolution

J. E. Cronin', N. T. Boaz', C. B. Stringer & Y. Rak

- * Department of Anthropology, Harvard University, Cambridge, Massachusetts 02138, USA

The nature of human evolution has been viewed recently as a specific example of a more general model of evolution termed 'punctuated equilibrium'. The characteristics of this model are long periods of little or no evolutionary change (stasis) interspersed with periods of rapid (punctuated) morphological change. Careful analysis of the hominid fossil record over the past 4.0 million years, however, suggests no well documented examples of either stasis or punctuation. The evidence for the evolution of the hominid lineage is most reasonably interpreted by a model of more gradual change with periods of varying rates of evolution.

THE evolution of populations through time occurs by changes in the constitution of the gene pool. The traditional viewpoint has been that most of the change along lineages is cumulative and gradual. This hypothesis of 'phyletic gradualism', proposes that if a complete fossil record of an evolving lineage were to be found, it would consist of a finely graded series of forms progressively more similar through time to descendent species and less and less similar to ancestral species. The temporally intermediate forms would be intermediate morphologically. The fact that morphological gaps appear between ancestral and descendant populations is a function of the imperfect nature of the fossil record.

This view of evolution has recently been questioned. It has instead been suggested that a substantial fraction of evolutionary change is concentrated in rapid bursts of speciation events. In the intervening periods most species exhibit slow, little, or no change at the morphological and genomic levels. The proponents of this theory suggest that phyletic gradualism plays very little part in the evolution of character states. The gaps in the fossil record are real and are the outcome of very rapid change from one form to another, thus leaving few or no intermediates in the fossil record. Speciation events occur in a short period of time, predominantly in geographically marginal populations with small effective breeding sizes. Thus the geological record is unlikely to preserve such saltations. This view of evolution has been termed punctuated equilibrium, or rectangular evolution.

Recently Gould and Eldredge¹ have argued that "a punctuational view of change may have wide validity at all levels of evolutionary processes" and have cited human evolution as a particularly good example of punctuated equilibrium. They state that "no gradualism has been detected within any hominid taxon, and many are long ranging".

It is our intention in this review to show that with more fossil evidence and better dating techniques than in the past, one can clearly demonstrate directional morphological change. There are fossils that appear clearly intermediate in form and time between recognized fossil hominid taxa. We review all the examples put forward by Gould and Eldredge in support of punctuated evolution in hominid evolution and conclude that a hypothesis of phyletic gradualism is more parsimonious. Furthermore we question the degree to which genetic studies support punctuation; changes at regulatory loci or chromosomal reorganization may have rapid and pronounced effects on

phenotype but the commonly observed allozymic changes cannot clearly be related to punctuational events.

Major stages of hominid evolution

Largely because of increased sample sizes and better dating (Fig. 1), there is better consensus than ever before on the major stages of hominid evolution through the Pliocene and Pleistocene. We will confine ourselves to examining the Plio-Pleistocene hominid fossil record for evidence of punctuational change and not try to argue for or against the various possible phylogenetic trees presented in Fig. 2.

The origin of the hominid family is a topic of continuing research. The hominid fossil record is largely nonexistent before 4 million years ago (4 Myr) and it is therefore uncertain how Pliocene hominids and Miocene hominoids are related²⁻⁴. The lack of Upper Miocene to Pliocene fossils precludes detailed discussion of absolute rates of evolutionary change. Biomolecular results indicate a date of 4-6 Myr for the pongid-hominid split⁵⁻⁷.

The earliest good sample of undoubted hominids comes from the Laetolil Beds of Tanzania^{8,9}, dated at between 3.5 and 3.8 Myr, close to the putative hominid-pongid separation predicted by macromolecular evidence. These and later samples from Hadar^{8,9} and early parts of the Omo sequence¹⁰ in Ethiopia, and from Makapansgat, Sterkfontein and perhaps Taung in South Africa¹⁰, dating from approximately 3 to over 2 Myr, comprise the known samples of early gracile australopithecines (Figs 1, 3).

The earliest appearance of the genus *Homo* is generally considered to have been between 2.2 and 1.8 Myr^{2,9,10-12}. Specimens attributable to *Homo* are known from the Lower Member of the Koobi Fora Formation¹³, Olduvai Bed I¹⁴, Omo Shungura Members E, F and G¹⁵, Swartkrans Member 1^{16,17} and Sterkfontein Member 5¹¹ in Africa and the Djetis levels (Putjangan Formation) in Java^{18,19}. The African sample has generally been referred to as *Homo habilis* L. Leakey, Tobias and Napier 1964, or simply *Homo* sp. ²⁰, while the earliest Javan hominids have been referred to as *Homo modjokertensis* von Koenigswald 1936. These two may be morphologically and temporally co-terminous ^{2,10,21,22}.

Based on the close congruence in the last appearance of A. africanus and the first appearance of Homo, and on the morphological continuities seen in the two taxa (Figs 1,3), an ancestral-descendant relationship between them has been widely, but not unanimously accepted 11.23-25. Opposition stems

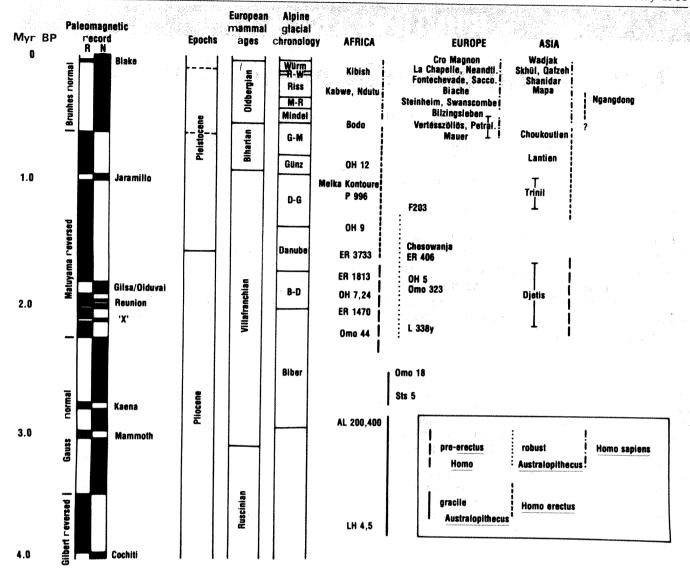

Fig. 1 Time scale and hominid lineages during the Plio-Pleistocene. Hominid fossils documenting stages along lineages are positioned according to their temporal locations. Large degrees of temporal uncertainty are indicated by error bars. The alpine glacial chronology is presented because of its historical importance rather than its accuracy. Some of the Choukoutien material may be considerably younger than shown here and in Fig. 3.

from those who believe that late surviving Australopithecus africanus or early occurring Homo²⁶⁻²⁸ preclude a simple ancestral-descendant relationship. Others divide the gracile australopithecines⁹.

Robust australopithecines were first recovered from the South African sites of Kromdraai and Swartkrans. This South African group is now referred to as Australopithecus robustus (Broom), 1938. The peculiar facial and dental morphology of A. robustus led Broom to believe that this hominid represented a side branch of human evolution.

In 1959 the type specimen of another robust hominid was discovered at Olduvai Gorge. This hominid, Australopithecus boisei, has since been found at other East African localities: Beds I, II and IV at Olduvai Gorge²⁹, Peninj (Humbu Formation)³⁰, Chesowanja (Chemoigut Formation)³¹, Lower and Upper Members of the Koobi Fora Formation²⁰ and Omo Shungura Members E, F, G and possibly H and L¹⁵.

The earliest appearances of the robust australopithecines in both East and South Africa seem to be at 2 Myr, and they persisted as late as 1.0 Myr^{2,32}.

The actual phylogenetic relationship of the robust lineage is widely debated. Some believe that the taxon A. africanus is directly ancestral to robust australopithecines (Fig. 2), with the former species showing shared derived morphological features

with the latter taxa. Others believe that this relationship has not been clearly demonstrated and that A. africanus provides a suitable candidate for a form that gives rise subsequently to the contemporaneous lineages Homo habilis and robust australopithecines².

The first remains of Homo erectus were discovered by Dubois in 1891. Assigned by him to the genus Pithecanthropus, these and subsequent discoveries from Java, China and Africa are now classified within the genus $Homo^{33}$. The morphology of the H. erectus material from Choukoutien, China (Fig. 3) was described by Weidenreich and this sample has provided the main data on the characteristics of this species³⁴⁻³⁷. Further important material has been recovered from Early and Middle Pleistocene deposits in Java, Middle Pleistocene deposits in Algeria and Early Pleistocene deposits at Olduvai and Koobi Fora³³ for the occurrence of this species in the Middle Pleistocene of Europe are overly dependent on the parts preserved in the various fossils and the characters which are utilized for classification—see discussion on the Petralona cranium below.) Recent definitions of this species have been provided by Le Gros Clark²³ and, in greater detail, by Howell¹⁰. Most anthropologists accept that H. erectus was ancestral to Homo sapiens. Specimens often quoted as displaying 'intermediate' or 'mosaic' characters between H. erectus and H. sapiens include Broken Hill and Omo

(Kibish) in Africa, Ngandong in Java, and Arago, Vertésszöllös and Petralona in Europe³³ (Fig. 3). Other recently discovered fossils which may belong to this intermediate category are the African Middle Pleistocene specimens from Sale³⁸, Ndutu^{29,39} and Bodo⁴⁰. However, not all palaeoanthropologists are convinced that *H. erectus* is ancestral to *H. sapiens*^{41,42,133}.

The term H. sapiens has recently been used to include various Middle and Late Pleistocene fossils which can be distinguished from H. erectus. Campbell introduced a system utilizing subspecific names for geographical or temporal sub-groups within *H. sapiens* ⁴³ and, rightly or wrongly, the subspecies name H.s. sapiens has become synonymous with anatomically modern humans in general. Some palaeoanthropologists have preferred the term 'archaic H. sapiens' for fossils considered more 'advanced' than H. erectus but still morphologically distinguishable from 'modern' H. sapiens44 (Fig. 3). Within the former category are the 'Neandertals', placed by Campbell⁴³ in the category H. sapiens neanderthalensis. Others have defined 'Neandertal' more broadly to include fossils from the Old World which they consider to be ancestral to modern humans throughout the Late Pleistocene range of H. sapiens^{25,45}. Yet others have attempted to subdivide the Late Pleistocene material using morphological criteria and have delineated 'Neandertals' as a group supposedly restricted to the earlier Late Pleistocene of Europe and western Asia, which can apparently be differentiated from penecontemporaneous fossils from Africa and eastern Asia 46-48.93. The origin of anatomically modern *H. sapiens* (whether from one restricted area or more widely) is still in dispute and lack of good fossil evidence from many parts of the Old World makes resolution of this problem more difficult.

Hominid fossil evidence and rates of evolution

Gould and Eldredge¹ suggested that the gaps in the fossil record should be treated as data, as though they were 'real' and not artefacts of the fossilization process. Thus the observation that intermediate forms between taxa are frequently not known is explained on the basis that evolution from one to another species occurred so rapidly that no transitional forms were preserved. The basic assumption here is that the fossil record is relatively complete.

Available data do not support Gould and Eldredge's assumption of a complete fossil record for the Hominidae.

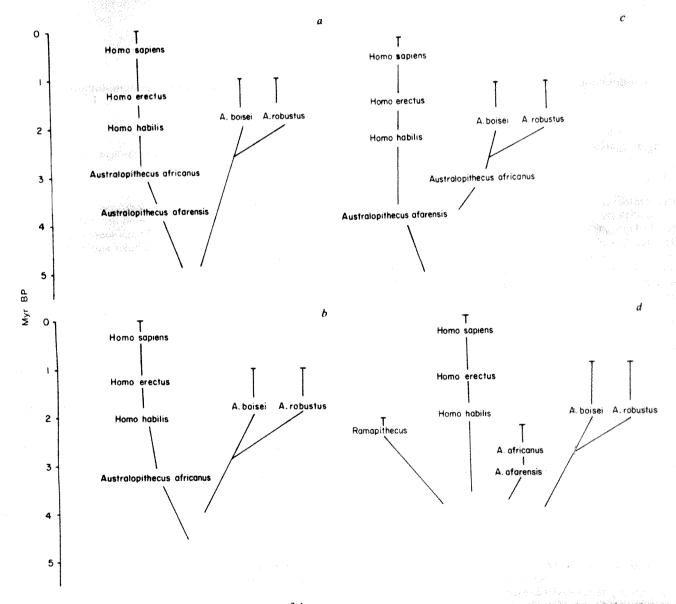

Fig. 2 Alternative phylogenies of the major hominid taxa²⁻⁴. Although not encompassing all proposed schemes, these four phylogenies are representative of the current most likely hypotheses. One of us (N.T.B.) favours phylogeny b, whereas another (Y.R.) favours phylogeny c. All of us concur, however, that A. africanus is not far removed from a basal australopithecine morphotype. The phylogeny sepresented in d is a polyphyletic hypothesis favoured by R.E.F. Leakey²⁷.

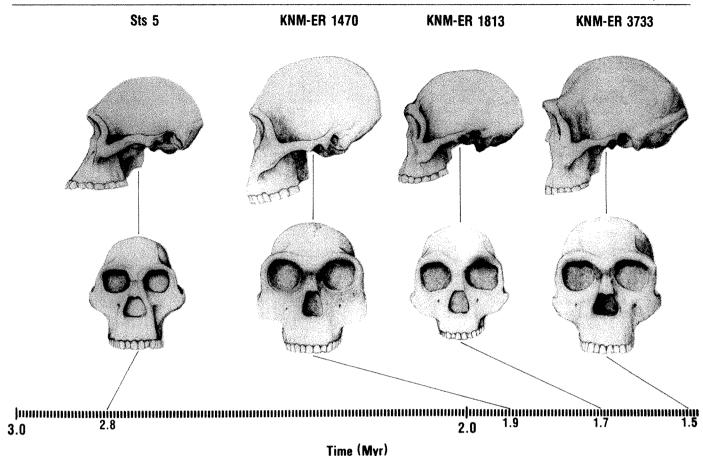

Fig. 3 Certain key hominid fossil crania in the 'gracile' hominid lineage through time, plotted along the bottom of the figure from left to right.

Behrensmever⁴⁹ estimates that only 4×10^{-5} of the original hominid population over a span of 1.5 Myr is represented at Koobi Fora. At Omo Shungura, with the longest sequence of hominid-bearing sediments yet known⁵⁰, 35 lithological units accounting for only 38.3% of the total vertical stratigraphical thickness have yielded hominid remains. If the total time represented by the Shungura Formation is almost 2.6 Myr¹⁰, this implies a loss of 1.6 Myr of time. Using an average of empirically derived population density estimates for Omo Hominidae (1.05 1, an area of 500 km² and a generation time for early hominids of 20 yr, the 215 known fossil hominid individuals from Omo Shungura derived from populations totalling $6.8 \times$ 10^7 individuals. Thus, the fossil sample represents a mere $3.2 \times$ 10⁻⁶ of the original population. In terms of both time represented and numbers of the original populations, the hominid fossil sample seems to be a very imperfect indication of the actual palaeobiology. In addition, the fragmentary nature of the preserved remains frequently does not allow phylogenetic interpretation. Thus there is almost no support for the assumption that the fossil record of hominids is complete, although a general overview of the major stages is possible while we await new fossil material.

Meanwhile recent sophisticated geochronological studies have provided sufficiently precise dates for existing fossil material to test the hypothesis of punctuated equilibrium. Two such tests are presented in Fig. 4. Means of body weight estimates and cranial capacity of the 'gracile' hominid lineage are plotted through time. The trends seem to show no jumps or discontinuities. Any impulse to draw a step diagram through the points should be resisted while the most parsimonious approach is to interpret the trends with a best-fit line.

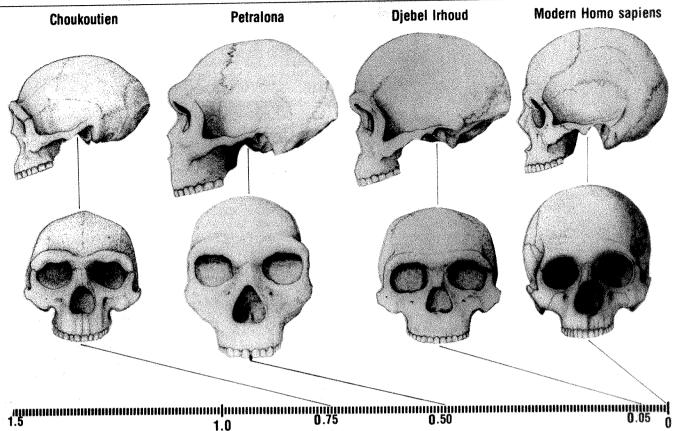

Gould⁵² has recently suggested that the supposed long temporal range of A. afarensis, based on a 3.7-3.8 Myr date on Laetoli and a 2.8-3.2 Myr date on Hadar, indicates morpholo-

gical stasis over time. Two considerations argue against this claim. The fossil remains from Laetoli are not abundant, and there are no diagnostic crania. Although some specimens in this sample do show dental and mandibular similarities to Hadar specimens, it is unknown to what degree the crania, which are taxonomically paramount for Hominidae, would correspond. Thus, a morphological argument for stasis cannot be sustained.

Second, while the K-Ar dating of tuffs at Laetoli and Hadar remain to be confirmed by other dating techniques, such as palaeomagnetism, there are preliminary faunal indications that Hadar and Laetoli may be closer in time than the absolute dates would suggest. Thus, a temporal argument for stasis within the proposed taxon A. afarensis is unconvincing.

A good case for phyletic gradualism within the gracile australopithecine lineage could be made from a comparison of South African A. africanus, with the more primitive and probably older A. afarensis. On the basis of the present samples, Hadar and Laetoli specimens evince generalized hominoid traits in having P3 mesiobucally set in the tooth row, large canines with distal longitudinal wear facets, I2-C diastemata and a relatively small cranial capacity9. They also possess certain derived traits in common with A. africanus from South Africa, particularly in the innominate and femur⁵³, face and cranial vault⁵⁴, and mandibular and dental morphology⁵⁵. Further fossil and geochronological evidence is needed to document the proposed transitional period from Laetoli and Hadar to classic A. africanus, but the balance of evidence does not support stasis within the Laetoli-Hadar samples through time nor punctuational change from these to A. africanus.

Two specimens of cardinal importance to the punctuated equilibrium argument come from the Koobi Fora Formation, Kenya (KNM-ER 1470 and KNM-ER 3733, ref. 20; Fig. 3; Table 1). The dating of these specimens is of paramount

Time (Myr)

Fig. 3 (cont.)

importance but faunal and geochronological dating of East Lake Turkana had been controversial until a recent solution was reached 56,63.

KMN-ER 1470 comes from the Lower Member of the Koobi Fora Formation, 37 m below the KBS Tuff in Area 131 (refs 20, 57, 58), and at an unknown distance above the Tulu Bor Tuff. The specimen has been dated on the basis of 40 Ar/ 39 Ar determinations on the overlying KBS Tuff, initially reported to be $2.6 \pm .26$ Myr BP⁵⁹. Leakey⁵⁷ claimed an age of 2.9 Myr BP for the find, adding $\sim 300,000$ for deposition of the 37 m of sediment separating ER 1470 and the KBS Tuff (12.3 cm per 1,000 yr). However, faunal studies^{60,61}, K-Ar redating of the KBS Tuff^{62,63}, tuff chemistry studies⁵⁶ and fission track dating⁶⁴ have now demonstrated that the KBS-131 Tuff is only ~ 1.8 Myr BP and is correlative with Tuff H-2 in the nearby Omo sequence at the same date. The sub-KBS fauna, which includes ER 1470, correlates with Omo levels about 2.0 Myr BP (refs 61, 65) and this is also the most likely date of KNM-ER 1470.

KNM-ER 3733 comes from the lower part of the Upper Member of the Koobi Fora Formation⁶⁶ in Area 104 (ref. 28), having been found in a sand infilling ~10 m above the post-KBS erosion surface⁶⁷. Another specimen, KNM-ER 1813, to be discussed below, comes from the upper Lower Member of Koobi Fora Formation in Area 123 (refs 13, 20), 8–10 m below the lateral correlative of the post-KBS erosion surface⁶⁷. ER 1813 is thus stratigraphically 18–20 m lower in the sequence than ER 3733. Assuming a sedimentation rate of 10–15 cm per 1,000 yr (60 m between the KBS Tuff and the overlying Chari Tuff 1.8–1.25 Myr), the difference in time between ER 3733 and ER 1813 is between 200,000 and 120,000 yr. Probable absolute dates are about 1.8 Myr BP for ER 1813 and 1.6 Myr BP for ER 3733.

Morphological and chronological arguments have been advanced to demonstrate the evolution of the earliest *Homo* from gracile australopithecines^{2,10}. Opponents of this view have held that *Homo* co-existed with gracile *Australopithecus*^{27,68}.

KMN-ER 1470, which has now been shown to have a spuriously old date, was a key part of this argument. It is a cranium lacking teeth but showing the large cranial vault, slight mid-facial prognathism, post-orbital expansion, relatively small temporal fossae and unpronounced supraorbital tori generally associated with the genus Homo. However, its relatively robustly constructed face, flattish naso-alveolar clivus (recalling australopithecine dished faces), low maximum cranial width (on the temporals), strong canine juga and large molars (as indicated by remaining roots) are all relatively primitive traits which ally the specimen with members of the taxon A. africanus. The specimen probably represents a member of the earliest species of the genus *Homo*, *H. habilis* (or *H. modjokertensis*^{2,22}), also known in Africa from Olduvai¹⁴, Omo⁶⁹, Sterkfontein⁷⁰ and Swartkrans¹⁶. KNM-ER 1470, like other early Homo specimens, shows many morphological characteristics in common with gracile australopithecines that are not shared with later specimens of the genus *Homo* (Table 1); in fact, Walker^{26,28} has classified ER 1470 as australopithecine. When accurately dated, and considering the morphology, ER 1470 supports the graduated evolution of Homo from a gracile australopithecine species in the later Pliocene.

Various authors^{8,9,55} have recently discussed these ancestral australopithecine populations. The Pliocene specimens, whether referable to the new taxon A. afarensis⁸ or to A. africanus² (Fig. 2), and undeniably primitive in their morphology, do show many characters which link them with later Homo (Table 1); M. D. Leakey⁶⁸ has in fact, classified them as Homo sp.

The gap between *H. habilis/modjokertensis* and *H. erectus* has now been filled by several important specimens, including KNM-ER 1813⁷¹. ER 1813 shows incipient supraorbital tori depressed in the glabellar region, a post-toral sulcus, a post-toral temporal ridge (similar to OH 9), a slightly more anteroposteriorly elongated cranium than specimens such as OH 13, a slight torus occipitalis and a mid-facial region slightly more

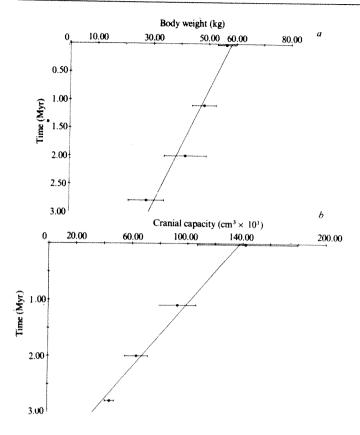

Fig. 4 a, Means of body weight estimates of hominid taxa in the 'gracile' lineage through time. The mean of A. africanus body weight estimates (27.7 kg) is plotted at 2.8 Myr BP and is an average of (in kg): 18.65, 25, 32 and 35.3 (refs 139, 140, 4, 141 respectively). The mean for H. habilits (41.8 kg) is plotted at 2.0 Myr BP and is an average of (in kg): 31.3, 40, 43 and 52.8 (refs 139, 140, 4, 141 respectively). The mean for H. erectus (48.5 kg) is plotted at 1.1 Myr BP and is an average of (in kg): 42.5, 50 and 53 (refs 139, 140, 4 respectively). The mean for H. sapiens (56.4 kg) is plotted at 0.0 Myr BP and is an average of (in kg): 52.2, 57.0 and 60 (refs 139, 140, 4 respectively). Bars represent 1 s.d. on each side of the mean. Regression line is BW = 58.25 - 9.9, r = -0.97, where BW is body weight and t is time in Myr. The trend appears to be gradual from A. africanus to H. sapiens.

b, Means of cranial capacity estimates of hominid taxa in the 'gracile' hominid lineage through time. Times for taxa are as in Fig. 4 legend. The mean of A. africanus (443 cm³) is from (in cm³): 450 for AL 288-1 and 385 for AL 166-9 (ref. 54); 485 for Sts 5, 436 for Sts 19/58, 428 for Sts 60 and Sts 71, 500 for MLD 1 and 435 for MLD 37/38 (ref. 139). The H. habilis mean is from '13° (in cm³): 687 for OH 7, 650 for OH 13, 590 for OH 24, 752 for ER 1470 and 509 for ER 1813. The H. erectus mean is from (in cm³): 1067 for OH 9, 727 for OH 12 (ref. 139) and 850 for ER 3733 (ref. 79); 850 for Sangiran 1, 775 for Sangiran 2, 890 for Sangiran 3, 750 for Sangiran 4, 975 for Sangiran 6, 915 for Sangiran 7, 1,030 for Ckt 2, 915 for Ckt 3, 1,225 for Ckt 10, 1,015 for Ckt 11 and 1,030 for Ckt 21 (ref. 140). The H. sapiens mean is estimated at 1,420 cm³ as midway between means for H.s. neander-thalensis 140 and H.s. sapiens 140. Bars for H. sapiens represent observed range 140 and for other taxa represent 1 s.d. on each side. Regression line is CC = 1378.6 - 352.1t, r = -0.99, where CC = cranial capacity and r = time in Myr. Similar results have been obtained by other authors 142.143.

prognathous than ER 1470. It nevertheless retains many early *Homo* characteristics such as lack of ectocranial crests, relatively straight nasals and a small temporal fossa. Its intermediate temporal position, as discussed above, and intermediate morphology can be interpreted as linking the earlier *Homo* populations and later *H. erectus*.

One *H. erectus* specimen from Koobi Fora (KNM-ER 3733) is claimed¹ to be earlier than non-African *H. erectus*, but morphologically within the range of Choukoutien *H. erectus*. Thus similarities between KNM-ER 3733 and Choukoutien *H. erectus* are said to provide an example of stasis after a rapid evolutionary speciation event. As discussed above, ER 3733 comes from the lower portion of the Upper Member of the

Koobi Fora Formation, with a probable date of about 1.6 Myr. If we exclude the Indonesian Putjangan specimens, it is older than other Old World H. erectus: OH 9, Bed II, Olduvai at 1.3 Myr BP (ref. 72); P996-17, Member K at Omo at 1.4 Myr (ref. 15). Trinil at ~ 1.3 Myr and later¹⁹; and Melka Kontoure at ~ 1.0 Myr BP (ref. 73). Choukoutien is not well dated radiometrically, but has been ascribed on faunal grounds to ages ranging from Early to Late Pleistocene 74. Fauna from the main hominid levels (such as Locus L, layers 8-9) is typically Middle Pleistocene and correlative with the European 'Cromerian'. Kahlke and Chou75 have reported Ailuropoda, Macaca robustus and Elephas cf. namadicus, taxa characteristic of the late Early Pleistocene and early Middle Pleistocene⁷⁶, from the lower hominid-bearing levels at Choukoutien. Kahlke⁷⁷ states that E. namadicus is part of the Asian Middle Pleistocene faunas which correlate indirectly with Süssenborn ('Mindel'-'Elster') faunas of eastern Europe. The Early/Middle Pleistocene boundary is now conventionally taken⁷⁸ as 0.69 Myr BP and on faunal grounds most of the Choukoutien hominids would post-date this datum. Although the entire assemblage spans a considerable time range, the main finds of Choukoutien H. erectus do in fact appear to be at least 0.8 Myr younger than ER 3733. On present evidence specimens attributed to H. erectus extend from about 1.6 to 0.6 Myr, or younger.

The available evidence does not support the hypothesis of morphological stasis in H. erectus through time. The peak in robusticity in the evolution of H. erectus did not occur with the earliest appearance of the species. The earliest examples of H. erectus possess a relatively longer and flatter face, shorter, thinner and less buttressed cranial vault, smaller cranial capacity, and a thinner and narrower supraorbital torus than later H. erectus. ER 3733, which is the earliest relatively complete example of H. erectus, falls outside and below the range for Choukoutien H. erectus fossils in four of the five measurements provided by Leakey and Walker⁶⁶. Its cranial capacity of about 850 cm3 (estimated by Holloway, quoted in ref. 79) is outside the Peking range (915-1,225 cm³)³³ and is closer to Javanese H. modjokertensis specimens. The supraorbital torus appears thinner than that of later H. erectus specimens such as OH 9, Sangiran 17 and the Choukoutien crania and recalls that of earlier fossil hominids ER 1470, ER 1813 and OH 24. The long, flat, vertically oriented face with a deep sub-nasal area is perhaps a retained primitive feature from an ancestor similar to ER 1470. Table 1 summarizes the morphological continuities to be seen from early to late H. erectus, thus vitiating Gould and Eldredge's contention of stasis in this clade¹

In the case of *H. sapiens*, Gould and Eldredge¹ imply that modern *Homo sapiens* is morphologically similar to the earliest examples of this species. This interpretation would be more defensible if they were referring only to anatomically modern man as *H. sapiens* because, for example, the earliest anatomically modern populations of Europe and Australia over 20,000 yr ago do closely resemble their present-day aboriginal counterparts ^{46,80}. But even here it can be argued that noticeable evolutionary change has occurred ^{81,82}. However, most anthropologists would extend the term *H. sapiens* to include various fossils from the Middle Pleistocene (such as Swanscombe, Steinheim, and Broken Hill) and the earlier Late Pleistocene (the Neandertals).

To test the alternative models of phyletic gradualism or punctuated equilibrium in the evolution of *H. sapiens* we require (as Gould and Eldredge state) reasonable samples with good stratigraphical control. The only area which approaches these conditions in terms of samples with good stratigraphical control is Europe. If phyletic gradualism is a reality and *H. erectus* was gradually transformed into 'archaic' H. sapiens and thence into 'modern' *H. sapiens*, then the earliest examples of *H. sapiens* should show *erectus*-like characteristics. The fossil record should progressively document the appearance of 'modern' features. Indeed, we might even expect there to be fossils with intermediate characteristics.

Table 1 Comparison of morphological traits, chosen on the basis of ability to differentiate hominid taxa, among four key specimens discussed in the text

This chart shows the mosaic pattern of evolutionary change in hominids, the clear directionality to be seen in a number of morphological traits, such as cranial capacity, and the fact that there are hominid fossils showing morphology intermediate between accepted hominid species.

* KMN-ER 1470, classified as H. habilis, shows nine traits which are either shared with A. africanus (Sts5, AL 288-1, MLD 37/38) or intermediate between this taxon and other H. habilis (OH 7, OH 13, OH 24, L 894-1, SK 847).

† KNM-ER 1813, a later H. habilis, shows 11 traits characteristic of H. erectus or intermediate between H. erectus and H. habilis.

‡ KNM-ER 3733, classified as early H. erectus, shows 11 traits shared with H. habilis or intermediate between this taxon and other (Asian) H. erectus.

§ The Petralona cranium classified here as an early H. sapiens shows 13 traits either shared with H. erectus or intermediate in morphology.

The European Middle Pleistocene record does provide us with such examples. The fossils from Mauer, Arago, Vertésszöllös, Petralona and Bilzingsleben have been regarded by various workers as belonging to either H. erectus or H. sapiens $^{33,43,45,46,83-85}$. The most complete of the specimens is the Petralona cranium, apparently associated with a Biharian (Cromerian) fauna which would place it as broadly con-temporaneous with the Mauer, Vertésszöllös and perhaps Choukoutien fossils, and earlier than the Bilzingsleben, Swanscombe and Steinheim specimens⁸⁴. If phyletic gradualism operated to transform H. erectus into H. sapiens, a specimen from the middle part of the Middle Pleistocene would be expected to show intermediate or mosaic characteristics when compared with the two species. Table 1 shows that the Petralona cranium displays characteristics typical of each species (if we can accept that Neandertals do in fact belong in the species H. sapiens). In features associated with cranial expansion and dental reduction, it is apparently intermediate. All the earlier Middle Pleistocene European specimens may belong in the species H. sapiens, but placing them within H. erectus would not alter their evolutionary significance. They differ as much from early H. erectus fossils as they do from late H. sapiens

Vlček⁸⁵ has claimed that during the Holsteinian of Europe, *H. erectus* (as at Bilzingsleben) co-existed with *H. sapiens* (as at Swanscombe and Steinheim). Apart from the important ques-

tion of morphological variability to be expected in the Middle Pleistocene, correlations in Europe are now so uncertain that 'Holsteinian' faunas may, in fact, span two or more distinct interglacials covering a period of some 200,000 yr (ref. 86), and a recent study of the Bilzingsleben site suggests that it dates from the penultimate interglacial in Europe rather than the Holsteinian⁸⁷. Similarly, Swanscombe may be separated by a considerable period of time from other sites in the 'Holsteinian' complex. Certainly the morphology of the Bilzingsleben specimens suggests that present concepts of variation within the species *H. erectus* and *H. sapiens* need to be re-examined ⁸⁸⁻⁹⁰.

In the fossil record of the later Pleistocene of Europe we meet the continuing problem of the place of 'Neandertals' in human evolution 91.144,155. Stringer 46 has discussed the European evidence for a gradual emergence of a Neandertal morphology during the later Middle Pleistocene and early Late Pleistocene. Fossils such as Swanscombe and Fontéchevade, previously regarded as part of a 'pre-sapiens' evolutionary lineage separate from that of the Neandertals, are probably part of an early Neandertal lineage. However, European Neandertals may not be the best candidates for the ancestors of anatomically modern H. sapiens in Europe during the middle part of the last glaciation 46.47, notwithstanding much support for the opposite view that there is an evolutionary continuity between these European populations 45.81.83. Until some of the critical specimens in this debate are conclusively dated and the functional significance of

some of the relevant morphological differences better understood, resolution of this problem may lie in the analysis of character states present in Neandertals and other contemporaneous populations 48,90-95.

Thus the evolution of anatomically modern man can at present support either the model of evolutionary gradualism or that of punctuated equilibrium, although the present evidence may favour discontinuity between Neandertal and 'modern' populations in Europe and Southwest Asia. Had Europe been a relatively peripheral area, gradualism in other areas could have led to the evolution of populations of anatomically modern H. sapiens whose genes could have infiltrated into Europe relatively rapidly, producing an apparent example of punctuated equilibrium in the European record.

Punctuated evolutionary change would imply a high variance in the durations or lifetimes of hominid taxa, as the appearance of new taxa is supposedly a function of a rapid and random event. If the taxa A. africanus extended from 3.2 to 2.2 Myr (1.0 Myr), H. habilis from 2.2 to 1.6 Myr (0.6 Myr), H. erectus from 1.6 to 0.6 Myr (1.0 Myr), and H. sapiens appeared at 0.6 Myr, then change does not seem to be dissimilar from one species to the next. If Laetoli A. afarensis at 3.7 Myr is accepted as a forerunner of A. africanus, this species further supports this pattern, with a known species lifetime of 0.5 Myr. For these five taxa, whatever their phylogenetic relationship, there is a mean duration of 0.74 ± 0.24 Myr, indicating similar species lifetimes, as may be expected in a gradualistic model. For an alternative interpretation see Stanley⁹⁶.

Possible cases of punctuated equilibrium in the hominid fossil record

The geologically sudden appearance of robust australopithecines in South and East Africa between 2.1 and 2.0 Myr seems to represent an obvious example of punctuation. The fact that their morphology appears so specialized supports this. However, on closer examination the robust lineage reveals a distinctly gradual trend of evolution. It is the highly specialized and hence accountable morphology of the 'final product' that enables one to recognize the direction of the evolutionary trend and to define the position of each fossil within the sequence.

Rak⁹⁷ explains this trend as related to the forward movement of the origin of the masticatory muscles away from the fulcrum (the articular eminence), on the one hand, and the tucking in of the dental arcade, on the other. Australopithecus boisei is the most evolved species of the sequence. However, some of the A. boisei specimens, whether studied through actual measurements or through observations of their topography, are found to fall within the range of the less specialized species, A. robustus. The direction of evolution of the masticatory system is also detected in the known sample of A. robustus. The topography observed on many fragments (mainly the infraorbital region) again indicates the existence of a morphological sequence. A. robustus and A. boisei are ordered in this sequence, although sufficient differences exist to justify their recognition as distinct taxa. The claims1 that 'there is no direct evidence for gradualism within any hominid taxon' and 'each species disappears looking much as it did at its origin' probably result from a familiarity with only the most well known specimens.

The known sample of A. robustus is probably contemporary with at least part of the time span of A. boisei. Morphologically, however, A. robustus would be expected to be an intermediate stage between the more general australopithecines and the more specialized, hyper-robust A. boisei. One hypothesis to explain the relationship between A. robustus and A. boisei is that the former represents a relic population that continued to exist in South Africa, representing the prototype from which A. boisei evolved.

Some of the specimens which make up the morphological range of species of Australopithecus, that is A. africanus, that existed 0.5 Myr earlier, resemble A. robustus very closely in topographical features of the face. The fairly complete fossil Sts

71 can be considered representative of the robust end of the morphological range, although fragments and isolated teeth of other specimens hint at the possiblity that even more robust individuals existed. Specimens from the other end of the range, such as Sts 52 and TM 1512, exhibit a quite generalized primitive morphology. Rak⁹⁷ suggests that A. africanus may have a greater morphological spread than the sample of A. robustus, not because the former is represented by a larger sample (it is not), but because a longer time span is covered by its sample.

Robust australopithecines probably evolved from earlier, more gracile hominids similar in morphology to A. africanus. Whether the known fossils of this taxon represent the actual ancestral population of later robust australopithecines is debatable (Fig. 2) but A. africanus is clearly morphologically closer to a common australopithecine ancestor than are robust australopithecines. Continuities to be seen from gracile to robust australopithecines therefore do not support a punctuational view of australopithecine evolution.

Other parts of the hominid fossil record suggest that stasis may have predominated over evolutionary change in certain peripheral areas. The Ngandong crania are supposedly Late Pleistocene in age⁷⁴ but show fundamental resemblances to much earlier *H. erectus* specimens^{46,98}. As with the Broken Hill specimen⁹⁹, this apparent Late Pleistocene anomaly may eventually be removed by evidence that the Ngandong fossils are, in fact, of Middle Pleistocene age; but at the moment these fossils provide one of the strongest examples of relative stasis in a peripheral and relict human popoulation.

Evidence from genetic studies

Genetic study of current populations is a major focus of attempts to elucidate patterns and mechanisms of speciation 100-103. The traditional view—that there are large genetic changes, or 'a

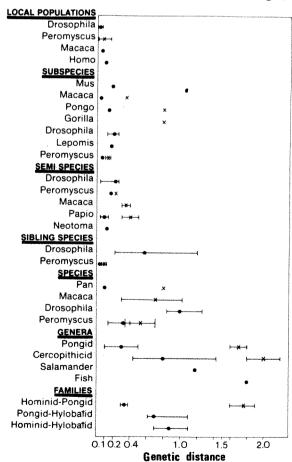

Fig. 5 Range of genetic distances (bottom axis) for the varying taxonomic levels as referenced in Table 2. ×, Fast loci; ●, typical mix of loci.

Table 2 Genetic distance values for taxa compared at different 'levels' of speciation

Addic 2			-		
		D typical	Genetic distance	D	fast
Taxon	Drosophila	Vertebrates	Primates	Peromyscus	Primates
Populations Sub-species Semi-species Species Genera	$0.02 \pm 0.012 \\ 0.186 \pm 0.057 \\ 0.226 \\ 0.451 \pm 0.329$	0.028 ± 0.02 0.163 ± 0.02 0.168 ± 0.01 0.319 ± 0.194 0.706 ± 0.319	0.011 ± 0.012 0.084 ± 0.048 0.163 ± 0.14 0.318 ± 0.233 0.631 ± 0.31	0.066 ± 0.06 0.139 ± 0.009 0.224 0.305 ± 0.257	0.30 ± 0.235 0.477 ± 0.239 0.4 ± 0.086 0.67 ± 0.276 1.36 ± 0.512

The term semi-species is defined by Mayr¹⁰² as species that were recently conspecific and subsequently speciated through geographical isolation and remain mostly allopatric. Hybridization does occur to differing extents (refs 7, 101, 115, 123, 124, 126, 127, 134–138, and J. E. C. and V. M. Sarich, unpublished observations).

genetic revolution', often accompanying speciation events—would be supported if the process occurred in small, peripheral or isolated populations 104-109. Various papers have reviewed the extent of genetic variation in natural populations 110,111 and genomic distances can be quantified between taxa 112,113. Gould and Eldredge have cited structural gene studies of allozymic differences between taxa of differing levels as the major criterion of their model. Ayala 114 and Avise 115 (Table 2) have indeed observed a gap between genetic distances as measured at both the local population level and at the level of sub- and semi-species but Lewontin 116 and White 101 find little genetic distance accumulating during speciation. Many species are less different genetically than populations within the same species, and morphological diversity may not correlate with genic divergence 101,117,118.

The apparent gap between populations and measures between sub- and semi-species is due to a differential weighing of loci with different function 119,120 and different rates of evolution 7,121. Work on primates 121-123 and on rodents 124 demonstrate that this gap disappears when fast-evolving loci are included in the study (Table 2, Fig. 5). In fact allozymic differences between taxa may be highly time-dependent and useful for divergence date estimates 6,7,121,122, an observation not compatible with suggestions of punctuation or genetic revolution.

Hence there is no obvious correlation between the degree of genetic differentiation and speciation; the development of reproductive isolation, by whatever mode, may be accompanied by little, some, or substantial allozymic change.

Electrophoresis of gene products may well be too insensitive a method to detect the genetic changes accompanying speciation. Nucleic acid hybridization shows that species differ by quantitatively small values of base-pair difference, much less than 1% in unique sequence DNA. Sub- and semi-species differ by even less 125.

So what is the genetic basis of speciation? Microgenic changes may result cumulatively in reproductive isolation. Single gene mutations at structural loci may have a profound effect on the phenotype and correspondingly to speciation events. Alternatively, not all genes may be involved in a genomic reorganization. A model of genetic 'transiliance' in which only a few polygenic systems each with major and minor genes undergo change is also possible. Thus a change in only a small fraction of the genes could contribute to a genomic revolution.

Also, true revolution may be found at the chromosomal level. Chromosomal rates of evolution seem to correlate with the degree of morphological evolution and rates of speciation ¹⁰⁷. Such change would be macrogenic and would best be sought at the level of satellite DNA, quantity of DNA per locus, chromosomal rearrangements and regulatory loci mutations ¹⁰¹.

Conclusions

We should not be surprised to find specific instances of explosive and gradual evolution at both the molecular and organismal level. The questions at hand are whether punctuation or saltation is the predominant mode of evolution as Gould and Eldredge assert¹, and whether human evolution is a case which confirms the general model of punctuated equilibrium at either the genetic or morphological level.

The specific course of genomic evolution along the hominid lineage can be conjectured. Since the time of divergence, humans and chimps have come to differ by about 1% at each gene¹²⁶, a value characteristic of differences generally found between sibling species^{122,126,127}. On the other hand, humans and chimps differ by some nine pericentric inversions¹²⁸. Fixation of such inversions is facilitated by low effective breeding size of populations or inbreeding ^{101,129}. Conditions for fixation of such inversions would be optimal during speciation by bottlenecking. Thus, it is highly probable that a few bottlenecks in effective breeding size, some resulting in speciation, without apparent major effects on the phenotype may have occurred along the hominid lineage.

Perhaps the most interesting area of evolution—the origins of the human lineage—can only be cautiously dealt with due to incomplete evidence. It may be the most likely period of time when rapid or explosive evolution may have occurred. The earliest undoubted hominids in the fossil record, from Hadar and Laetoli9, are quite primitive and date to somewhat less than 4.0 Myr. The molecular clock suggests a hominid-pongid divergence somewhat before this 6.7. Thus, the hominid transition could have been characterized by extremely rapid morphological change (the evolution of bipedality), and by a period of low population numbers, or bottlenecks, with most of chromosomal evolution, genic reorganization, or allelic substitutions occurring in rapid sequence. It is here that the evidence fails us in being particularly incomplete, only partially suggestive and open to many different interpretations 130,131, and it may be that as more evidence becomes available even this possible case of punctuation may be like the cheshire cat and disappear until only its smile is left.

In summary, the evidence that we, unlike some others 96,132,133, have adduced from the fossil record does not support the model of punctuated equilibrium for hominid evolution. Apparent cases of punctuated equilibrium in the fossil record of hominids are due to one of three causes. Specimens are certainly misdated, as in the case of KNM-ER 1470, possibly or probably misdated, such as the Ngandong specimens, or open to very different morphological interpretations, for example, regarding KNM-ER 1813 as a gracile australopithecine versus a member of the genus Homo. A review of the morphology of hominid fossils with their most probable dates strongly suggests a closer approximation to a gradualistic model. There is demonstrable change within hominid taxa through time as well as continuities from one species to its supposed descendent species. There is little or no support for the belief that the hominid fossil record is complete. Thus gaps in the record are most likely artefacts of the processes of fossilization and discovery and not true palaeobiological discontinuities. Further assessment of the model of punctuated equilibrium must await a more rigorous definition of such parameters as the temporal difference between punctuation and fast gradualism and the degree of morphological change considered to constitute either a gap or stasis. If a finer, continuous analysis were possible, it

would probably reveal that gradualism is, itself, an average of periods of horotely (fast change) and bradytely (slow change). Evolution of the Hominidae is still most reasonably interpreted by a model of phyletic gradualism with varying rates.

We thank M. Billig, L. Brunker, R. Happel, K. Janszen, R. Dorit, E. Meikle and S. L. Washburn for helpful discussions and for comments on previous drafts of the manuscripts, F. C.

ARTICLES

Depth of geological contrast across the West African craton margin

J. C. Briden, D. N. Whitcombe, G. W. Stuart & J. D. Fairhead

Department of Earth Sciences, The University of Leeds, Leeds LS2 9JT, UK

C. Dorbath & L. Dorbath

Office de la Récherche Scientifique et Technique Outre-Mer, 24 Rue Bayard, 75008 Paris, France

Anomalies in teleseismic arrivals at stations astride the West African Craton margin in Senegal are large and systematic for rays which have passed beneath the craton margin. Lateral variation in seismic velocity structure beneath the margin persists to several hundred kilometres depth. The major relative delay time and slowness—azimuth anomalies fit a simple model of a steep boundary in the mantle aligned with the major gravity anomaly associated with the craton margin. The mantle beneath the Mauritanide orogenic belt has lower P-velocity than the adjacent craton between ~80 and 220 km, but higher average velocity both above and below that depth range.

IF mantle structure could simply be categorized as subcontinental and sub-oceanic, there would be no consensus over whether lateral differences persist to depths greater than ~ 220 km (refs 1-5). Seismological and other evidence indicate a more complex regional characterization of mantle structure. Significant lateral differences occur down to at least 500 km in the vicinity of many active subduction zones^{6,7}. Theory of formation of orogenic belts at convergent plate margins requires the persistence of subduction, and hence of lateral variations to great depths, throughout the period of orogenesis. Surface wave data from Tertiary⁸ and older orogenic belts⁹ suggest that shear wave velocity structure beneath such belts differs from that beneath both ancient cratons and modern oceans. Global and regional teleseismic delay times 10,11 and heat flow 12,13 have been taken to indicate lithospheric thicknesses > 200 km in places. Thus differences which arose at the time of orogenesis have persisted for hundreds of millions of years after the cessation of orogenic activity so that determination of present-day seismic structure of ancient orogenic belts may clarify the geodynamics of orogenesis.

We report here preliminary results for temporary teleseismic arrays laid out across the junction of a Precambrian craton with a Phanerozoic orogenic belt to detect lateral differences in mantle seismic velocity structure and to determine whether a boundary between these two regions is detectable to mantle depths.

Location and design of field experiment

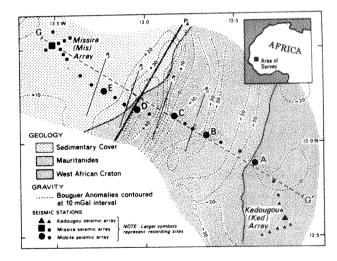

Figure 1 shows the site of the experiment in Eastern Senegal, where the western margin of the West African craton ($\sim 2,000$ Myr and older) abuts the Mauritanide orogenic belt of late Palaeozoic age (~ 250 Myr).

There are differences of up to 1.0 s in teleseismic delay times between seismic stations on the craton (Kedougou, Fig. 1) and on the orogenic belt¹⁴. The major long-wavelength Bouguer gravity anomaly¹⁵ parallel to the craton margin is characteristic of many craton margins elsewhere ^{16,17}. These data suggest that lateral differences across the margin may persist at least into the uppermost mantle.

Two short period vertical (SPz) seismic arrays, each of 20 km aperture, were operated for 6 months: the L-shaped nine station Kedougou (Ked) array on the craton and the cross-shaped eight station Missira (Mis) array centred 180 km to the north-west on the orogenic belt provided travel-time and slowness-data necessary for three-dimensional interpretation of the structure beneath and between them. A mobile linear array of three or four SPz seismometers was placed for 1 month in each of five

successive positions A-E (Fig. 1) to provide records at 10-km spacing along the whole profile between the Ked and Mis arrays. A multichannel analogue tape recorder at the central station of each array recorded an adjacent three component set of short-period seismometers and a single vertical long-period seismometer together with the radio-telemetered signals from the outstations of each array. The internal time base of each recorder was made absolute by recording time signals from BBC World Service transmissions.

All recorded events were digitized at 50 samples per s, and relative arrival times were picked by waveform matching producing overall accuracy of better than 0.05 s. Epicentral

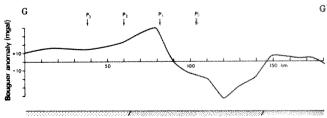

Fig. 1 Part of Senegal, showing the seismic arrays, the Bouguer gravity contours 15, and the Bouguer anomaly profile along the line GG'. Po to P4 are examined positions of a postulated boundary separating cratonic and orogenic velocity structures.

information was taken from USGS PDE bulletins and predicted arrival times were computed utilizing the programme GEDESS¹⁸ with the Jeffreys-Bullen travel-time tables¹⁹. To date 550 seismic events have been identified on the analogue tapes, of which 330 originated in the teleseismic P window, 120 were core phases and the remainder were of local origin. This report considers a subset of the SPz records at the main Ked and Mis arrays, of teleseismic events for which delay times and apparent velocities have been determined, together with some delay time data from the mobile array.

Results

The delay time differences between the central stations of the Mis and Ked arrays are plotted as a function of epicentral distance and azimuth in Fig. 2a. The main features are: rays into the Mis array on the orogenic belt from almost all azimuths and teleseismic distances are slower (positive delays) relative to those into the Ked array on the craton. However, the magnitude of the delays is sensitive to distance and azimuth; between azimuths of $\sim 40^\circ$ and 70° there is a rapid decrease in relative delay time from +0.8 to -0.2 s. The maximum relative delays (+0.8 s) occur for events from the north-east. For westerly azimuths, the delay times decrease with increasing distance from 0.7 s at $\Delta = 60^\circ$ to 0.3 s at $\Delta = 80^\circ$. The relative delays have also been determined for a set of PKIKP core phases in the distance ranges $174^\circ < \Delta < 178^\circ$ and show a similar constant delay of +0.3 s.

Variations of relative delay time along the whole profile are shown in Fig. 3. Each nuclear test site (Fig. 3a-c) can be regarded as a single repeated source. The Kazakh data (Fig.

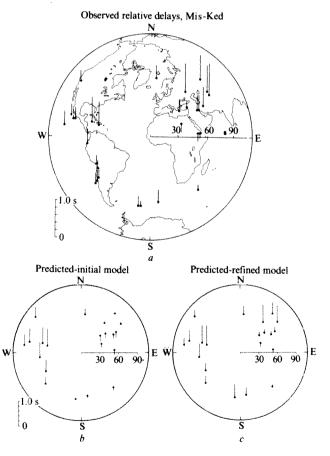

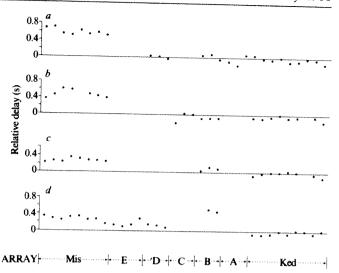

Fig. 2 Teleseismic delay time differences Mis-Ked between the Missira and Kedougou arrays as a function of the position of the source; a, observed; b, predicted by ray tracing through the starting model of Fig. 6a in which the craton boundary is at position P_3 and vertical; c, predicted by ray tracing through the refined model of Fig. 6b in which the craton boundary is at position P_2 and dips at 85° to the west.

1965

3a, b) show a sharp westerly increase in relative delay within array E, ~ 80 km west of the outcropping margin. The PKIKP phases (Fig. 3d) have all travelled by similar paths through the receiver structure; they do not show the same pattern of relative delay, though they do show an anomalous (though poorly defined) delay within array B.

Slowness-azimuth anomalies at the Ked array (Fig. 4b) are small and non-systematic from all azimuths except the west; for westerly paths (for rays which have passed beneath the craton-orogenic margin) slownesses are anomalously high and seem to have been refracted across a structure striking NNE. At the Mis array the dominant feature (Fig. 4a) is southerly slowness-azimuth anomalies which are thought to be due to a northerly dipping sedimentary-basement interface.

When the effect of this interface is 'stripped-off' rays from only two sectors appear anomalous (Fig. 4c). Northeasterly arrivals, which have traversed beneath the craton margin, seem to have been perturbed by a NNW-striking structure—slowness being anomalously low for the steepest arrivals but anomalously high for arrivals at larger incidence. Anomalies which persist for azimuths close to 280° could be due to lateral variation in the deep structure of the orogenic belt.

Two-dimensional velocity models

Because the regional strike of the gravity anomaly, the craton margin and the orogenic structure are generally constant and the slowness anomalies follow their local variation, we can treat the seismic data two-dimensionally on a regional scale. In our velocity models we adopt a compromise strike of our models (P_0-P_3) between the trends of the segments of the line P_4 in Fig. 5.

Models of crustal structure which would produce the observed anomalies all have unacceptable features, notably large lateral velocity contrasts and/or Moho topography which are incompatible with the observed gravity field across the arrays. Hence velocity differences must extend into the upper mantle. The craton has predominantly the higher velocity structure because vertically travelling core phases through the sub-orogenic structure are delayed by 0.3 s. We treat the structure beneath the Mis and Ked arrays as essentially horizontally layered because these arrays are clear of the craton margin and its associated gravity anomaly, and except for ray paths which pass beneath the craton margin, the slowness-azimuth anomaly patterns do not suggest inclined layering at depths²⁰. For such models the azimuth-distance dependence of relative delay times and the drastic change in direction of the slowness-azimuth anomaly vectors for northeasterly arrivals into Mis, both require

Ked array Mis array Mis array stripped Mis array Ked array modelled modelled

Fig. 4 Slowness anomalies for a. Missira; and b, Kedougou arrays²⁰ Expected slowness. Anomalies generated at a single interface are orthogonal to the strike of that interface. In c the effect of basement topography dipping at 348° azimuth is stripped-off by subtraction of a vector 1.7 s deg^{-1} in that direction. In d and e the observations in c and b are modelled by ray tracthrough the velocity structure of Fig. 6c in the position indicated in Fig. 5.

that between certain depth ranges the orogenic belt has the higher seismic velocity structure. The abrupt change in relative delay times along the profile (Fig. 3) and its marked variation with azimuth (Fig. 2a) require that the transition between the sub-cratonic and sub-orogenic velocity structure is both sharp and steep even at mantle depths.

Two-layer models which account for these anomalous features cannot also account for the negative relative delay times for easterly ray paths (Fig. 2a); these can be accommodated if the orogenic crust is thinner and/or has higher velocity than the cratonic crust. Thus to explain all the main features of the data, we need a model with a minimum of three 'layers' in the crust and upper mantle in which the laterally uniform sub-craton and sub-orogen velocity structures are separated by a near vertical boundary; the top and bottom layers have the higher average velocities beneath the orogenic belt and the middle layer has the higher velocity beneath the craton.

Each layer i delays an arrival travelling through the suborogenic structure by a time a, relative to an arrival travelling through the same layer in the sub-cratonic structure: thus a_2 will be positive while a_1 and a_3 are negative. Vertically-travelling core phases travel entirely in either sub-orogenic and subcratonic velocity structures, so that $a_1 + a_2 + a_3 = 0.3$ s. The same relative delay terms a, apply to inclined teleseismic paths, errors due to non-verticality being negligible. The relative delays for these inclined paths will depend on the amount of mixing of the rays through the two structures. For example, the high relative delay of +0.8 s from the north-east is interpreted as being due to rays into Mis crossing the model boundary near the bottom of the middle layer: hence $a_1 + a_2 = 0.8$ s. Similarly, negative relative delays for rays from the east which cross the boundary within the top layer, make $a_1 = -0.2$ s. Thus $a_2 =$ 1.0 s and $a_3 = -0.5$ s.

If h_i is the thickness of the *i*th layer then a_i is related to the

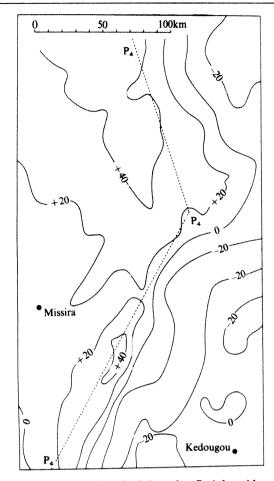

Fig. 5 The position of the seismic boundary P_4 , inferred from the slowness models (Fig. 4d, e) superimposed on the Bouguer anomaly map¹⁵.

average velocities V_{oi} and V_{ci} within that layer beneath the craton and orogen respectively by

$$a_i = h_i \left(\frac{1}{V_{oi}} - \frac{1}{V_{ci}} \right)$$

hence

$$\frac{\delta V_i}{V_i} \simeq \frac{V_i a}{h_i}$$

where V_i is the average velocity within layer i and $\delta V_i = V_{ci} - V_{oi}$.

Interpretation of the data requires the thickness of the layers and the position of the boundary to be determined. To satisfy the slowness anomalies and delay time variations from westerly azimuths, rays to Ked from the west must cross the boundary across a negative velocity contrast (within the bottom layer). The largest positive delay times for rays into Mis from easterly azimuths must cross the boundary near the base of layer 2. These two constraints can be met if the boundary at depth occurs west of its outcropping position—a conclusion supported by the nuclear explosion profile data (Fig. 3). More easterly estimates of the position of this boundary lead to contradictory depth estimates for westerly and northeasterly ray-path data. With the boundary at P3 (Fig. 1) the thickness of the top layer is estimated at 80 km to account for the ray paths which show a relative delay of -0.2 s, assuming that they cross the boundary at the base of layer 1. Arrivals at Ked from the west, with anomalously large slowness, cross such a boundary in the depth range 220-390 km while those to Mis with relative delays of 0.8 s cross the boundary at ~240 km. Hence the base of layer 2 is taken at 230 km and that of layer 3 at 400 km for our starting model. This definition of model layer thicknesses h_i constrains the velocity contrasts in each layer to be -1.7%, +5.4% and -2.8% respectively.

This starting model (Fig. 6a) may now be refined to reconcile all the relative delay time data and to allow for refraction across the boundary, using a 'shooting' ray tracing technique²¹. The fit of predicted and observed delay times for arrivals from the east is further improved by dividing the top layer into two (Fig. 6b). An inadequacy of the starting model is that signals from East Kazakhstan would be internally reflected at the boundary before reaching Mis. This problem would not exist with a lower velocity contrast in the bottom layer, or if the strike of the boundary were bent as in Fig. 5, or if the boundary were inclined at a small angle to the vertical so that it is dipping beneath the orogen. The teleseismic delay times are sensitive to the inclination of the boundary, as rays are travelling steeply through the model. It is difficult to satisfy the large relative delays from the north-east with the smaller relative delays from the west unless the dip of the boundary deviates from the vertical. The refined model (Fig. 6b), which has the surface expression of the boundary at P2, and the dip of the contact as 85° towards the west, displays the main features of the observed relative delay time pattern: compare Fig. 2c with Fig. 2a.

To investigate further the interdependence of model parameters, the relative delay times have been directly inverted by a modification of the least squares technique of Aki et al. ²². This modification divides each layer of the model into two to simulate sub-cratonic and sub-orogenic structure. The block boundary, which need not be vertical, thus simulates the actual lateral velocity discontinuity within each layer. The travel time of each ray through each block is calculated using three-dimensional ray tracing ²¹. This inversion method mimics the tectonic regionalizations common for surface wave dispersion studies ²³. The trial models allowed for velocity differences down to 400 km, either side of a vertical or near vertical boundary in positions P_0 , P_1 , P_2 and P_3 (Fig. 1).

The lowest solution variance occurred with the boundary at a position P_2 , and dipping beneath the orogenic belt between 85° and 80°. This solution accommodated $\sim 80\%$ of the observed data variance. Ray tracing through this inversion model yields predicted delay times similar to those of Fig. 2c. The most consistent feature of all the solutions with variance close to the minimum is the region in which the sub-cratonic structure has the higher velocity: this occurs at a depth $80-200 \, \mathrm{km}$ if the boundary is at the preferred position P_2 consistent with the

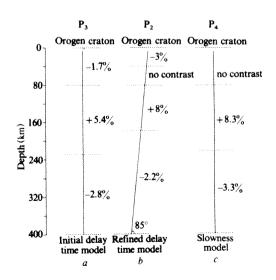

Fig. 6 Velocity contrast models obtained by forward modelling using three-dimensional ray tracing. For all these models the boundary between the craton and orogenic velocity structure is assumed to be planar and positioned at P2, P3 or P4 (see Fig. 1). The dip of the boundary is represented to true scale. The contrasts in the slowness model c must be greater to explain the magnitude of the observed slowness anomalies in Fig. 4.

deductions from forward ray tracing. If the boundary were only 20 km to the east (P1) the equivalent layer would be displaced downwards by 40 km; a comparable upward displacement of this layer would be inferred if the boundary lay 20 km to the west (P₃).

All solutions tend to show higher average velocities beneath the orogenic belt below this layer down to 400 km (layer 3 in the ray tracing modelling). However, neither this 'layer' nor the detailed velocity structure within it is well defined, probably because the velocity perturbations are small and comparable with their standard errors.

Although the inversions do not define a top layer as clearly as the ray tracing approach they do suggest a faster velocity structure within the top 80 km beneath the orogenic belt as inferred from ray tracings. The velocity perturbations determined by the inversions are all smaller than the equivalent velocity perturbations obtained by ray tracing. Simulated data have demonstrated that this inversion method can underestimate the magnitude of velocity anomalies.

Aspects of three-dimensional modelling

The slowness-azimuth anomaly patterns (Fig. 4b, c) require that their causative structure should not be precisely linear. A seismic boundary positioned along the line P4 in Fig. 5 gives a 'best' fit to the data in conjunction with the velocity contrast model in Fig. 6c in that it reproduces the magnitude and direction of the slowness anomalies for westerly paths into Kedougou and the antiparallel slowness anomaly for the NNW event (Fig. 4e) and reproduces the size, orientation and (to some extent) azimuth dependence of the slowness anomalies from the north-east quadrant into Missira (Fig. 4d). Because the line P4 was chosen on the basis of the seismic data, the concordance of its strike with that of the Bouguer anomaly (Fig. 5) is noteworthy. (The coincidence of its position in Fig. 5 is of less significance because position and dip of the model boundary and depths of the layers are to some extent mutually traded-off in the search for acceptable models.)

Although the teleseismic P and PKIKP data recorded by the end-arrays are fitted well by the models, the isolated observation of large relative delays for a PKIKP event recorded within subarray B (Fig. 3d) is not predicted, and the more complex model required must await more data, notably from the mobile

Tectonic interpretation of the seismic models

The contrast in background Bouguer anomaly between the craton and the orogenic belt (Fig. 1) is consistent with the cratonic crust being either thicker or having lower average density (and seismic velocity) than the orogenic crust, and hence is consistent with the uppermost part of the seismic model (Fig. 6).

The seismically-determined craton margin at depth lies $\sim \! 80$ km west of the outcropping margin, implying at least that amount of thrusting and/or depositional overlap of the rocks of the orogenic belt onto the craton. This intervening terrain is composed of a metamorphic belt (correlating with the linear positive Bouguer anomaly) and a zone of unmetamorphosed sediments and volcanics (correlating with the negative Bouguer anomaly, and pinching out with it in the north of Senegal); these correlations suggest that the causes of the linear Bouguer anomalies are within the overlap-overthrust rocks of the upper crust.

The major seismic velocity contrasts along the profile occur within the depth range ~80-200 km where the sub-cratonic structure is the faster by ~6%. This result is consistent with delay time inversion studies of lateral differences between older and younger orogenic regions in North America^{3,24} and in Europe²⁵ with the older structures having the higher velocities. The depth range 80-200 km also correlates well with the S-wave low velocity zone determined by the inversion of surface waves beneath aseismic continents²⁶. We thus prefer to ascribe the 6% P velocity contrast to a low velocity sub-orogenic structure rather than to an anomalously high velocity subcratonic structure.

At depths ≥ 200 km the younger, sub-orogenic, structure has the higher velocity, although the contrast is not as marked $(\sim 3\%)$. It may be argued that such a small contrast may be a random fluctuation in velocity, and not correlatable with the tectonics. However, studies in North America and Europe 3,24,25 have revealed similar features: cratonic North America has 2-3% lower velocity in the depth range 250-400 km than both the Appalachians and Western Cordillera. Similarly the Precambrian Grenville Province has lower velocities than the Palaeozoic Appalachian Province for the depth range 200-350 km (ref. 24). Within Europe in the depth range 250-400 km the P-wave velocity beneath the Alps is up to 2% higher than beneath adjacent areas²⁵. Furthermore the interpretation of NORSAR travel-time data using the Herglotz-Wiechert inversion technique indicates that the Baltic craton has higher velocities than orogenic Europe down to 300 km, while in the depth range 300-420 km it has the lower velocities²⁷

Because of the difficulties²⁹ of determining the depth of origin of teleseismic travel time anomalies, it is worth emphasizing that the principal grounds of our identification of deep lateral variations are: (1) the large epicentral dependence of relative delay times of ~1.0 s require lateral variations in upper mantle structure; (2) slowness anomaly vectors orthogonal to the local strike of the long wavelength gravity anomaly and craton margin imply that the seismic anomalies are inherently associated with that margin. Furthermore a reversal of the anomaly vectors at each array provides direct evidence for a velocity contrast reversal with depth. Such a model will accurately predict the major delay time anomalies.

If density contrasts at depth alternate then isostatic compensation depths may be much deeper (~400 km) than hitherto suspected. The gravity anomaly observed at surface may be regarded as the sum of several individual anomalies of alternate sign, generated in alternate depth zones: because these contributions will partially cancel each other out, the observed anomaly will not fully reflect the magnitude and extent of sub-surface contrasts. Relative teleseismic delay times for vertical paths to cratonic and orogenic stations show a similar effect if the boundary is near vertical: if we had taken delay times for vertical paths only or calculated a mean delay time for each station we would have inferred much less contrast and our models would not have extended to such great depths. It is the larger differential delay times from inclined ray paths which allow this deeper structure to be recognized.

It is beyond the scope of this article to speculate on the possible origin of a mantle boundary such as that inferred here, extending essentially vertically to 400 km into the mantle, but some preliminary points are worth noting. For example, where the lithospheric thickness exceeds ~300 km most sources of continental magmatism must be travelling with the lithospheric plate and must evolve with time, with or without replenishing mechanisms. If lithospheric thickness is variable, then the asthenosphere has considerable topography and variable thickness which would act as controls on plate motion. The near vertical attitude of a boundary within the upper mantle is not obviously compatible with an origin either at a compressional plate margin or an extensional margin; explanations may have to be sought in relation to transcurrent tectonics³⁰ (as has been suggested for the north-west margin of the West African craton on palaeomagnetic grounds³¹) or ideas about the deep thermal structure of plate margins may need revising.

Purified λ regulatory protein cII positively activates promoters for lysogenic development

Hiroyuki Shimatake & Martin Rosenberg

Laboratory of Biochemistry, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

The bacteriophage λ regulatory protein, cII, has been purified and shown to activate positively RNA transcription from the two phage promoters which coordinately regulate phage lysogenic development. To obtain this protein, the cII gene was cloned into a plasmid vector carrying the strong, regulatable λ phage promoter P_L such that it was overproduced to levels approaching 5% of cellular protein.

WHEN bacteriophage λ infects Escherichia coli cells, the phage can either grow lytically, resulting in the formation of new progeny virus particles which are released on lysis of the host cell, or the phage may enter a state of lysogeny, in which the viral DNA integrates into the host genome and the expression of lytic functions is repressed. In normal physiological conditions, a balance between lytic and lysogenic growth is achieved and appreciable numbers of cells enter both developmental path-

The establishment of the lysogenic state requires the synthesis of two phage functions—repressor (cI), a protein which inhibits transcription of lytic functions, and integrase (int), a protein which catalyses the integrative recombination between the viral DNA and the host genome. The production of both proteins is positively regulated by the phage gene products cII and cIII and also affected by various host-encoded functions 5,6. The synthesis of repressor and integrase is coordinately controlled at the level of transcription from the two λ promoters P_E and P_I (Fig. 1). The DNA structure of these two sites has been determined⁷⁻¹⁰ and their location precisely defined 11,12. Little is known, however, about the precise roles of the cII and cIII gene products in this activation process. In particular, it is not known whether cII works alone or in combination with other factors or whether cII works directly or indirectly to activate transcription from PE and P₁. Only by purifying the components and reconstituting the positive activation system in vitro can we hope to elucidate the role of cII and understand positive activation at these two promoters.

Cloning a 'lethal' gene function

During a normal λ infection, cII protein is synthesized for only a short time and seems to be rapidly turned-over¹³. Thus we set out to clone the \(\lambda \) cII gene into a plasmid vector in such a way that the gene would be efficiently and continually expressed. The general approach involved inserting a 1,300-base pair (bp) DNA fragment carrying the cII gene into a plasmid vector, in such a way that the cII coding region was positioned in proper orientation downstream from an efficient promoter signal for RNA transcription. We reasoned that efficient transcriptional expression of cII from the multicopy vector would result in high-level cII production. The purified 1,300-bp DNA fragment^{7,14} was inserted into several different derivatives of pBR322, each of which contained a known promoter signal of

either phage or bacterial origin positioned upstream from the site of insertion. Recombinants (Amp') were screened by size and restriction analysis for the presence of the fragment. Among multiple independent isolates (>10) which contained the insert, all had the fragment positioned with the cII coding region in opposite orientation to the direction of transcription. It appeared that transcriptional expression of the fragment gave rise to some lethal function.

This contention was supported by the facts that cleavage of the fragment at the single HincII restriction site within the cII gene now allowed each subfragment to be cloned downstream from the promoter signal, and that the entire fragment was readily inserted in both orientations into a pBR322 derivative lacking the promoter.

To circumvent these problems we reasoned that the cII gene (as well as any other lethal function) would have to be cloned such that its expression could be regulated. Thus we utilized a pBR322 derivative, pKC30, which contained a \(\lambda \) DNA fragment carrying the highly efficient promoter signal P_L (Fig. 1). This promoter can be regulated by the λ repressor protein (cI), a product which is synthesized continually and is regulated autogenously in an E. coli & lysogen15. A HpaI restriction site unique to pKC30 (Fig. 1) is located 321bp downstream from the startsite of P_L transcription. The 1,300-bp DNA fragment carrying the cII gene was inserted into this site and transformants (Amp^r) were selected in an E. coli λ lysogen. In contrast to our initial results, recombinants were now obtained carrying the intact 1,300-bp DNA fragment positioned in both possible orientations relative to P_L-directed transcription. The desired recombinant, pKC30cII, carries the cII gene oriented correctly with respect to P_L transcription, whereas the recombinant pKC30IIc carries the same fragment inserted in reverse orientation. When these plasmids were used to retransform both lysogenic and non-lysogenic E. coli strains, pKC30IIc transformed both strains with high efficiency, whereas pKC30cII only transformed the lysogen with high efficiency and was unable to transform the non-lysogen. Apparently, the amount of repressor being synthesized in the single lysogen is sufficient to reduce cII expression in the pKC30cII derivative to a non-lethal level.

To express the cII gene product in the lysogen, it was necessary to induce (derepress) the P_L promoter, by using a lysogen which carried a temperature-sensitive mutation in the phage repressor gene $(c1857)^{16}$. Thus, raising the temperature of these

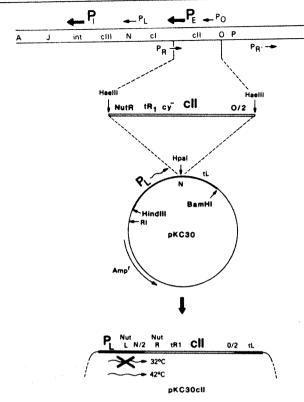

Fig. 1 Top: partial genetic map of bacteriophage λ . The locations of the positively regulated promoters, PE and PI, are indicated. These promoters are responsible for the coordinate expression of the phage lysogenic functions, repressor (cI) and integrase (int), respectively. Other major A promoters are also shown (P_R, P_L, P_O, P_R) . Expanded below is the region encompassed by a 1,300-bp HaeII DNA restriction fragment, which contains the cll gene and several other previously characterized phage regulatory sites (see below). Bottom: diagram of the construction of the plasmid vector which overproduces cII protein (pKC30cII). The HaelII restriction fragment was inserted into the single Hpal restriction site which occurs on the plasmid pKC30. This fragment contains the proposed site of recognition for the antitermination function N (NutR), the rho-dependent transcription termination site (tR1), The P_E promoter mutation cy3048 (cy⁻), the cII coding region and the amino-terminal half of the O gene $(0/2)^{7.18.24.25}$. The pKC30 plasmid is a derivative of plasmid pBR322 which contains a HindIII-BamHI restriction fragment derived from phage \(\lambda \) inserted between the HindIII and BamHI restriction sites within the tetracycline gene of pBR322 (R. N. Rao, unpublished data). The \(\lambda\) insert contains the promoter signal, PL, another proposed site of N recognition (NutL), the N gene and the strong rho-dependent transcription termination signal, tL^2 The HpaI restriction site occurs within the N gene coding region²⁰. Purific . Purified HaeIII fragment (0.1 pmol) and HpaI-cleaved pKC30 plasmid (0.1 pmol) were blunt-end ligated36 at 15 °C for 14 h and recleaved with HpaI after ligation. This DNA was used to transform a \(\lambda\) lysogen carrying a temperature-sensitive mutation (cI857) in its repressor gene. Ampr recombinants were obtained and screened by size and restriction for the presence of the insert. Recombinants were obtained carrying the insert in both possible orientations (described in text). Note that the final pKC30cII construction contains the transcription regulatory sites. NutL. NutR and tR1, preceding the cII gene. Preliminary studies indicate that high-level protein expression requires that the lysogen carry a functional N gene which is induced by temperature (A. Shatzman and M.R., unpublished). This N gene product presumably functions at the Nut sites to antiterminate transcription at tR1.

cells (from 32 to 41 °C) inactivates the repressor, thereby turning on transcription from the P_L promoter (Fig. 1). We had now achieved the desired construction: the cII gene had been inserted into a high-copy number plasmid vector and was positioned downstream from a strong, regulated promoter signal.

High-level production and purification of the cII gene product

Lysogens carrying either the pKC30cII plasmid or the control plasmid pKC30IIc were examined for their ability to synthesize proteins in response to temperature induction. Cells were initially grown at 32 °C and then pulse-labelled with ³⁵S-Met before and at various times after induction at 42 °C (Fig. 2). Total cellular protein from each pulse was then characterized by electrophoresis on SDS-polyacrylamide slab gels. The results

(Fig. 2A) indicate that two major polypeptides (of molecular weights (M,s) 10,500 and 32,000 respectively) are synthesized selectively in the pKC30cII lysogen in response to the temperature shift (pKC30cII lanes g-l). Neither of these polypeptides are made in the lysogen carrying pKC30IIc.

The molecular weight of the smaller peptide is appropriate to that expected for the cII gene product, as predicted by the DNA sequence of the cII coding region¹⁷. Moreover, this protein migrates identically with a polypeptide produced in a cell-free protein-synthesizing system (Fig. 2A, lane a) previously identified as cII (ref. 18 and C. Queen, unpublished results). The fact that the appearance of this polypeptide also depends on the correct orientation of the cII coding region and the temperature induction identifies this protein as the cII gene product.

The other polypeptide induced in the pKC30cII lysogen is probably a fusion peptide which derives from the O gene region of phage λ . The 1,300-bp DNA fragment inserted into the plasmid also contains information for the N-terminal 286 amino acids of the λ O gene¹⁹. The DNA sequence surrounding the HpaI fusion site²⁰ predicts that 14 additional in-frame translatable codons will be added to the 286 derived from the O gene before a translation termination codon occurs in frame. Thus, the P_L transcript from pKC30cII encodes a 300-amino acid O gene fusion product (32,000- M_T band) in addition to the cII gene product (the 10,500 band).

The intensities of the cII and O fusion products indicate that they are being synthesized at high rates relative to the other cellular products (Fig. 2A, lanes g, h). As cII is thought to be a relatively unstable protein¹³, we next examined whether the high rate of synthesis would lead to an accumulation of the cII protein in the cell. Again, lysogens carrying either pKC30cII or pKC30IIc were grown at 32 °C and temperature induced. After induction, total cellular protein was characterized on SDSpolyacrylamide gels and the major accumulated proteins detected by staining (Fig. 2B, lanes c, d). The cII and O fusion products were readily identified and found as major accumulated products in the pKC30cII lysogen (Fig. 2B, lane c). In these conditions cII protein was estimated to represent some 4-5% of total cellular protein. The cII protein was purified to ~98% homogeneity using standard procedures (Fig. 2B, lanes a, b). A detailed description of the isolation procedure and physical characterization of the protein will be given elsewhere (Y. Ho, H. S. and M. R., in preparation).

The procedure used here to clone, overproduce and obtain the cII protein (as well as the O gene fusion peptide) should have general application to the production and isolation of other proteins in bacterial cells. Of particular interest might be those products whose overproduction proves lethal to the cell21. The fact that the multiple copies of the highly efficient P_L promotor can be regulated in the single-copy lysogen allows cells to be grown initially without expression of the cloned function and then subsequently induced to produce the gene product. The rapidity of the induction procedure (1-1.5 h for maximum cII production) ensures maximum expression of the function within a relatively short time period. The system is readily adaptable to the production of almost any gene product (prokaryotic, eukaryotic or synthetic) provided the DNA insert contains all the necessary information for translating the product in the bacterial cell. A similar cloning vehicle has been used to overproduce the bacterial trp A gene product²².

cII-dependent transcription from promoters P_E and P_I

We next examined the ability of RNA polymerase, in the presence and absence of pure cII protein, to interact with and initiate transcription from the P_E and P_I promoters. We initially used a nitrocellulose filter binding assay to monitor the interaction, because RNA polymerase binds to DNA fragments containing promoters and forms heparin-resistant complexes which can be trapped on the filter 23 . Our assay results (Table 1) indicated that RNA polymerase alone cannot form a stable initiation complex at the P_E site. In fact, the DNA fragment

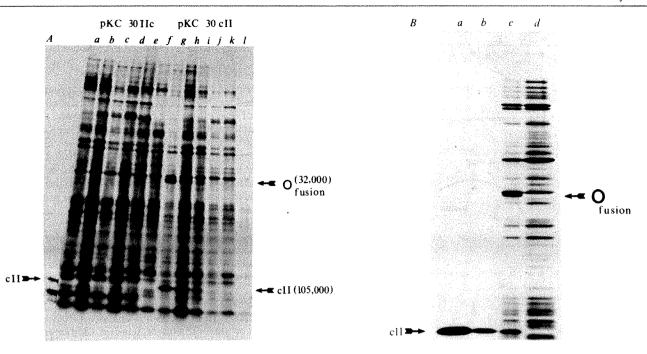

Fig. 2 A, autoradiogram of an SDS-polyacrylamide gel electrophoretic analysis of pulse-labelled proteins made in a λcl857 lysogen carrying either pKC30cII (lanes g-l) or pKC30IIc (lanes a-f) at various times after heat induction. Cells were grown at 32 °C in minimal media (M56 supplemented with 0.5% glycerol and 25 μg ml⁻¹ ampicillin)³⁷. At A₆₅₀ = 0.35 the temperature was raised to 42 °C. Aliquots (50 μl) of these cells were pulse-labelled for 45 s with ³⁵S-methionine (Amersham, 1,000 Ci mmol⁻¹) immediately before (lanes f, l) and at 5 (lanes e, k), 10 (lane e, i), 30 (lane b, h) and 40 (lanes a, g) min after heat induction. After pulse labelling, the cells were frozen (dry ice bath) and precipitated with trichloroacetic acid (final concentration 10%). The precipitate was resuspended in sample buffer (30 μl, 5.0 M urea, 0.1 M dithiothreitol, 1% SDS), boiled at 95 °C for 5 min, and subjected to electrophoresis on a polyacrylamide gradient slab gel (10% acrylamide, 0.25% bisacrylamide to 26% acrylamide, 0.325% bis-acrylamide) containing 0.1% SDS. The gels were dried and fluorographed³⁸. Lane a contains an ³⁵S-labelled marker polypeptide synthesized in a cell-free protein-synthesizing system and previously identified as the cll gene translation product (ref. 18 and C. Queen, unpublished data). Molecular weights are shown in parentheses. B, an SDS-polyacrylamide gel analysis of proteins accumulated in a cl857 lysogen carrying either pKC30flf (c) following a 40-min heat induction. Cells were initially grown at 32 °C as described above and at A₆₅₀ = 0.7, the temperature was raised to 42 °C for 40 min. Aliquots of these cells were analysed as above except that after electrophoresis the gel was stained with Coomassie brilliant blue R-250. The amount of clI was estimated by scanning the stained gel with a laser scanning densitometer (Zeineh). To purify the clI protein, cells transformed with pKC30clI (c) bluomided for 40 min at 42 °C. Cells were pelleted (8g), frozen and thawed, and then resuspended in

The 1,300-bp DNA fragment (Fig. 1) was cleaved with restriction endonuclease HincII and the products labelled at their 5' termini with T4 polynucleotide kinase (Boehringer-Mannheim) and $[\gamma^{-32}P]ATP$ (ICN, 2,000 Ci mmol⁻¹)³⁴. The resulting fragments of 400 and 900 bp, which contain the PE and Po promoters respectively, were separated by electrophoresis on a 4% polyacrylamide slab gel and recovered in pure form by electroelution. End-labelled fragments were prepared identically from either λ wild-type DNA (cy^+) or from mutant derivatives of λ carrying single base pair changes in the P_E promoter signal (cyL3048) and cyR3008, Fig. 5 and ref. 25). Transcription initiation complexes were formed by incubating the appropriate fragment (in the presence of 0.5 µg carrier DNA) with RNA polymerase (1.0 µg, Enzo Biochemicals) and/or cII protein (0.3 µg) in a 50 µl transcription reaction mixture (25 mM Tris-HCl pH 7.9, 80 mM KCl, 10 mM MgCl₂, 1 mM dithiothreitol) lacking the four nucleoside triphosphates. Reactions were incubated for 10 min at 37 °C and then heparin (final concentration $100~\mu g~ml^{-1})$ was added and after 2 min the mixture passed through a nitrocellulose filter (Schleicher and Schuell B6). The filter was washed with 500 µl of transcription buffer and counted, and the percentage of counts retained on the filter determined (100% = 5,000 c.p.m.).

containing P_E was not filter bound by either RNA polymerase or cII protein alone, whereas a control fragment carrying the phage promoter, P_O , was retained. When RNA polymerase and cII protein were combined, however, the P_E fragment was retained on the filter, suggesting that cII protein is required for RNA polymerase interaction at P_E . To prove that the binding was P_E specific, the experiment was repeated using the same DNA fragment obtained from two different phage derivatives carrying P_E point mutations 24,25 . One is a single base change in the -10 region of the promoter (cyL3048) and the other is a base change in the -35 region of the promoter (cyR3008). Each mutation eliminated filter binding (Table 1). Thus, the cII-dependent RNA polymerase interaction is specific for the wild-type P_E site.

We also examined the effect of cII on the ability of RNA polymerase to initiate transcription from either the PE or PI promoters in a purified in vitro transcription reaction. Transcriptions were carried out either in the presence or absence of purified cII protein using several different DNA templates. Two of these templates were constructed by inserting a \(\lambda \) DNA fragment carrying either P_E or P_I into the plasmid pBR322 (Fig. 3). Before transcription each template was cut with a restriction endonuclease such that RNA polymerase initiating at either PE or P₁ and proceeding to the end of the fragment would give rise to a discrete 'run-off' transcript. For each template a major RNA transcript of the expected size was obtained and its appearance depended completely on the presence of cII in the reaction (Fig. 4a, b). Several other discrete RNA products were obtained which apparently derive from other promoter signals contained on these plasmid derivatives (such as Pamp Ptet, Prep,

The PE and PI transcripts were labelled in vitro with the indicated ³²P]-nucleotides and gel-purified. After recovery from the gel, the following analyses were performed. RNA was digested in separate reactions with ribonucleases P1 and T2 and the products resolved by one-dimensional electrophoresis on DE81 paper at pH 1.7 (refs 27, 35). The products were identified by their relative mobilities using appropriate markers. The numbers given in parentheses indicate the relative molar yield of each product (determined by scintillation counting of the product after its detection by autoradiography). RNA was also digested with T₁ ribonuclease and the products separated by two-dimensional fingerprinting procedures²⁷. The first dimension was electrophoresis on strips of Cellogel (Kalex) at pH 3.5. The second dimension was homochromatography on TLC plates of DEAE cellulose (Analtech) using homosolvent B. The 5'-terminal oligonucleotide was identified after digestion of each T₁ oligonucleotide with pancreatic ribonuclease and electrophoretic separation of the products in one dimension on DE81 paper at pH 3.5 (ref. 27). ND, not determined.

* Indicates the labelled phosphate.

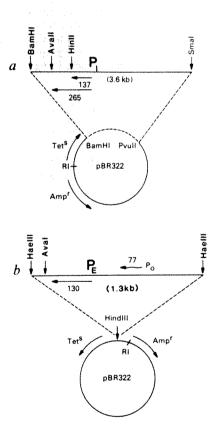

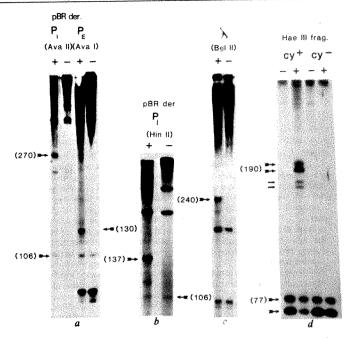

Fig. 3 Diagram of the plasmids used as DNA templates for in vitro RNA transcription. a, The 3,600-bp SmaI-BamHI λ DNA fragment containing P_I was inserted between the PvuII-BamHI site of pBR322. This plasmid was constructed in our laboratory by U. Schmeissner (unpublished data). b, The 1,300-bp HaeIII fragment (Fig. 1) containing P_E was inserted into the HindIII restriction site of pBR322 using HindII synthetic linkers (Collaborative Research). Note that this fragment also contains the P₀ promoter from which the 77 nucleotide-long RNA is transcribed (Fig. 4a, c and d)^{7,39}. Restriction enzyme cleavage sites are indicated and their respective distances from the P_I and P_E promoters noted when important to the description in the text.

Autoradiograms of polyacrylamide-gel electrophoretic analyses of ²P-labelled RNA transcripts synthesized in vitro from several different DNA templates either in the presence (+) or absence (-) of purified cII protein. Molecular weights ($\times 10^3$) are shown in parentheses. a, The pBR332 derivatives shown in Fig. 3a (carrying P1) and b (carrying PE) were cleaved with restriction endonucleases AvaII and AvaI, respectively, and used as templates. The cII-dependent 270 nucleotide-long P1 transcript and the 130-nucleotide-long PE transcript are indicated. Also indicated is the 106 nucleotide-long transcript which derives from the P_{rep} promoter located hear the replication origin of the plasmid⁴⁰. b, The pHR322 derivative shown in Fig. 3a (carrying P₁) was cleaved with HinII and used as template. The cII-dependent 137 nucleotide-long Pi transcript is indicated. The longer discrete transcripts seen in this gel are RNAs which presumably initiated at Pamp and Pter promoters. c, A DNA was cleaved with BglII and used as template. The cII-dependent 240 nucleotide-long Pg-initiated RNA is indicated. d, The purified 1,300-bp & HaeII restriction fragment (Fig. 1) obtained from either wild-type phage (cy*) or phage carrying the cy3048 point mutation in the P_E promoter (cy⁻) was used as template. The cIIdependent 190 nucleotide-long $P_{\rm E}$ transcript is indicated as well as the 77 nucleotide-long RNA. All DNA templates were transcribed and analysed on 4 or 5% polyacrylamide slab gels which contained 8 M urea as previously described7. The transcription reaction mixture (50 µl; as in Table 1 legend) contained the DNA template (0.5-2 µg), E. coli RNA polymerase holoenzyme (3-5 μ g; Enzo Biochemicals) the four nucleoside triphosphates (each at 200 μ M) and [α^{-3} P]ATP, -UTP or -GTP (Amersham, specific activity 300 Ci mmol⁻¹). When present, cII protein was added to a final concentration of 10-20 µg ml⁻¹ and all reactions were carried out at 37 °C for

Fig. 4). These transcripts were unaffected by the presence of cII in the reaction. Thus, cII selectively activates transcription from the P_I and P_E promoters.

The dependence of P_E transcription on cII was also demonstrated using a phage λ DNA template. Total λ DNA was cleaved with restriction endonuclease BgIII, which cleaves λ six times²⁶. One of these cleavage sites occurs 240bp downstream from P_E (ref. 14). In vitro transcription of the BgIII-cut template resulted in the appearance of a cII-dependent RNA product ~240 nucleotides long (Fig. 4c). Two other well characterized λ RNA transcripts were also resolved from these reactions: the 77 nucleotide-long P_O -initiated RNA and the 192 nucleotide-long P_R -initiated RNA. The transcription of both these RNAs was unaffected by cII. In an analogous experiment using λ DNA cut with restriction endonuclease AvaII (which cuts 265 bp downstream from P_I), we observed the predicted cII-dependent P_I -initiated transcript (data not shown).

We also examined the effect of a point mutation in the $P_{\rm E}$ promoter on the ability to synthesize the cII-dependent transcript. The 1,300-bp HaeIII DNA restriction fragment (Fig. 1) was obtained either from wild-type λ (cy⁺) or from a mutant derivative (cyL3048), and used as template. Transcription of the cy⁺ DNA resulted in a major cII-dependent transcript ~190 nucleotides long (actually a doublet, Fig. 4d). The size of this RNA is consistent with the distance between $P_{\rm E}$ and the HaeIII

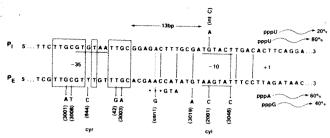

Fig. 5 Comparison of the DNA sequence of the $P_{\rm r}$ (refs 8-10) and $P_{\rm E}$ (refs , 11, 25) promoters. Only the non-template strands are shown cII-dependent transcription startsites used in vitro are indicated. Also shown (underlined) are the sequences in the -10 region of both promoters and in the -35 region of the P₁ promoter which exhibit some homology to the conserved sequence found in other promoters for E. coli RNA polymerase³². The boxed regions indicate 11 of 14 base pairs in the -35 regions of these two promoters which are identical. Note that the distance between the region of homology and the transcription startsites is exactly the same in each promoter. This region of homology has been proposed to be the site of positive activation 11,25. The various cyR and c-yL mutations which eliminate PE promoter function are indicated and also the can't mutation which has no effect on P_E promoter function but does not alter the second codon of the cII structural gene²⁵. The ATG initiation codon cII translation is also shown (on the opposite strand). The intC mutation^{8.9} which occurs in the -10 region of the P₁ promoter and confers cII-independent, constitutive expression of int gene is designated.

end of the fragment. Two-dimensional T₁-fingerprint analyses identified both of the RNAs in the doublet as transcripts which initiated at the P_E site. The cy point mutation eliminated all cII-dependent P_E transcription (Fig. 4d).

Note that the cII requirement for transcription from both the P_{I} and P_{E} sites seems absolute. This is in contrast to transcription observed at other promoters which are positively regulated (such as P_{lac} , P_{gal} , P_{RM})²⁷⁻²⁹. Even in the absence of the positive effector some level of transcription, albeit low, is usually observed. Moreover, this low-level transcription can be increased by including glycerol in the transcription reaction³⁰. This is not the case for P_E and P_I; addition of glycerol (up to 25% v/v) in the absence of cII protein resulted in no detectable P_I or P_E transcription (data not shown).

Fingerprint identification and 5'-terminal nucleotide analyses

The identification of the in vitro synthesized cII-dependent RNAs as transcripts derived from the PE and PI promoters was confirmed by two-dimensional T₁-oligonucleotide fingerprint analysis (data not shown, see Table 2 and refs 7, 31). The T_1 oligonucleotides obtained from these fingerprints were compared and found to be identical to those predicted from the known DNA sequence of the regions immediately downstream from the $P_{\rm E}$ and $P_{\rm I}$ promoters⁷⁻¹⁰. In addition, we precisely positioned and quantified the 5'-terminal transcription startsites used in vitro by RNA polymerase at P_E and P_I (Table 2). The results indicate that the cII-dependent \overline{P}_{E} transcript initiates in vitro from the same sites used in vivo¹¹, predominantly with pppA (60%) and less often with the adjacent pppG (40%) (Fig. 5). Analogously, the cII-dependent P₁ transcript also initiates in vitro from two adjacent sites, one major (80%) and one minor (20%), using in both cases a UTP starting nucleotide (Fig. 5). Again, the in vitro startsite coincides precisely with that demonstrated in vivo 12 and constitutes the first demonstration both in vitro and in vivo of the use by RNA polymerase of a uridine triphosphate as the initiating nucleotide.

Conclusions

We have described the cloning, overproduction and isolation of the λ cII gene product and demonstrated the general potential of this vector system for overproducing gene products which may be either lethal to the cell or rapidly turned-over. We have also shown that cII protein alone functions as the positive effector and turns on transcription from the two phage λ promoters, P_E and P_I, required for lysogenic development.

A variety of other phage and cellular factors have been

implicated in the transcriptional activation process of λ repressor and integrase expression^{2,3}. Speculations abound concerning the possible parts played by these various components in the PE and P₁ activation mechanism. Our present finding, that cII protein and RNA polymerase alone are both necessary and sufficient to turn on PE and P1 transcription in vitro, strongly implies that these other factors are likely to exert their effects only in an indirect fashion.

The DNA structure which encodes the P_E promoter site also encodes the ribosome binding site information and the Nterminal coding region of the cII protein (Fig. 5). We previously speculated that if cII protein were the positive activator of PE transcription, then its site of action would overlap with its own translational regulating and coding information7. This is now clearly the situation. We also proposed that the positive effector would probably interact at P_E in the -35 region^{11,25}, because of (1) the complete lack of any $P_{\rm E}$ -35 region homology with other known promoter sites³²; (2) the nature and positions of the -35 region mutations associated with $P_{\rm E}$ (cyR mutations); and (3) the extensive -35 region homologies exhibited between P_E and P_I (Fig. 5). Recent experiments designed to probe the ability of cII to protect the PE region from DNase cleavage (footprinting indicate that cII is a DNA binding protein which interacts specifically in the -35 region of the P_E site (Y. Ho and M. R., in preparation). Apparently our ability to obtain cII in large quantity and demonstrate its function as a positive effector molecule now allows us to study directly the potential interactions of this protein with itself, the DNA template and RNA polymerase.

We thank Dr R. N. Rao for providing us with the plasmid pKC30, Dr U. Schmeissner for construction of the pBR322 derivative containing the P₁ promoter site, C. Brady for technical assistance, R. Steinberg for photographic work, and P. Donoghue and G. Taff for typing and editing the manuscript.

The galaxy MCG8-11-11 inside the 0.093 square degrees error-box of the X-ray source 2A0551+466 (ref. 1), was recently found to be a Type 1 Seyfert galaxy2. A 40-arcs error-box from the A3 experiment on HEAO 1 has confined the X-ray emission to the nucleus or bar of this 14-m, galaxy3. The redshift is z = 0.0205 (ref. 2), corresponding to a distance of 123 Mpc $(H_0 = 50 \text{ km s}^{-1} \text{ Mpc}^{-1})$. The 2-10 keV luminosity ranges from $5 \times 10^{43} \text{erg s}^{-1}$ to $1.2 \times 10^{44} \text{erg s}^{-1}$ (refs 1, 3). Hard X-ray emission above 20 keV from the region of MCG8-11-11 has been recently reported4, and the A2 experiment on HEAO 1 has provided for the first time the emission spectrum of this object up to 30 keV (ref. 5). During a balloon flight on 30 September 1979 from Palestine, Texas of the Milan/Southampton (MISO) low-energy γ -ray telescope, an excess at the 3.9σ level in the flux above 90 keV was detected from a region of the sky containing MCG8-11-11. The emission spectrum, evaluated in the energy range 0.02-19 MeV, has similar spectral characteristics to those observed with the same telescope and associated with the Seyfert galaxy NGC4151 (ref. 6). Both spectra show evidence for a high-energy cutoff close to 3 MeV and this feature could be interpreted on the basis of the 'Penrose-Compton scattering' process⁷. A large amount of the observed low-energy γ-ray diffuse background8 could be produced by a few per cent of the X-ray emitting Seyfert galaxies having a γ-ray luminosity comparable with that observed from the region of NGC4151 or MCG8-11-11.

The MISO telescope⁹ consists of a 'Compton-coincidence' detection system inside a semi-active shield. The sensitive area is about 560 cm² and the aperture is 3° FWHM in both the azimuthal and zenithal planes. For the September 1979 flight, the energy range was set to be 0.05–19 MeV. A passively shielded hard X-ray detector (20–280 keV) having an effective area of 600 cm² and the same field of view of 3° FWHM was mounted parallel with the main telescope. A two-axis orientation system was used to point the telescope with a precision of about 0.3°.

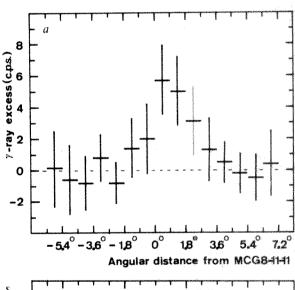

The region of the sky containing MCG8 -11-11 was studied on 30 September 1979 between 8 h 34 min UT and 14 h 59 min UT. Five drift-scans were performed to survey the region contained within the coordinate points RA 5 h 14 min and 6 h 33 min and centred on dec $+46.2^{\circ}$. The mean float altitude during the on-source periods was equivalent to an atmospheric pressure of about 4.2 mbar and the telescope was set at zenith angles between 16° and 33°.

To minimize systematic variations in the background due to changes in the zenith and azimuth of the telescope, the data for each scan were analysed separately and the results statistically combined. The only significant source of systematic variation in the background was found to be linearly related to the changes of the residual atmospheric pressure between 3.7 and 4.5 mbar. For each separate scan the background, corrected for the atmospheric pressure variation, was subtracted from the

measured on-source counting-rate. A mean excess of 3.3 ± 0.85 c.p.s. above 90 keV (2.9 ± 0.8 c.p.s. above 260 keV from the γ -ray telescope) was found when the data from the five drift-scans were combined.

In Fig. 1a, the correlation between the counting-rate excess above 260 keV and the angular distance between the estimated direction of MCG8 $-11 - \overline{1}1$ and the axis of the MISO telescope is shown. The error-box for the observed y-ray excess is plotted in right ascension and declination (for the 1950 equinox) in Fig. 1b together with the 4U and HEAO 1 (A2)⁵ error-boxes. The Ariel 5 error box1 has about the same dimension of the filled circle showing the position of MCG8-11-11. The limits of our error-box are represented by the 1σ points along the scanning direction, and by the total aperture of the telescope (6°) in the orthogonal direction, which represents the 100% probability of containing the emitting object. The uncertainty due to the pointing system has been included. The only X-ray source within our error-box, even if extended up to the 4σ level, is MCG8-11-11, apart from the OSO 7 source 1M0600+46 (ref. 10) for which the projection on the sky of the 1.14 square degrees error-box is not available.

The same method of analysis was used to evaluate the contribution of the source in individual energy-loss channels of both the main telescope and the hard X-ray detector, between 20 keV

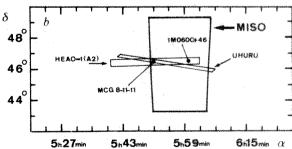

Fig. 1 a, γ -ray excess count rate above 260 keV versus the angle between the axis of the MISO telescope and the estimated direction of MCG8-11-11. b, The MISO error-box in right ascension and declination (for the 1950 equinox) is shown together with other astronomical data. The error-box of the OSO 7 X-ray source 1M 0600+46 (ref. 10) is not available. The Ariel 5 error-box of the X-ray source 2A 0551+466 (ref. 1) has about the same dimension of the filled circle showing the position of MCG8-11-11. The MISO error-box has 68% probability across the scan direction and 100% across the other. The uncertainty due to the pointing system has been included.

and 19 MeV. A photon spectrum at the top of the atmosphere was obtained by means of a matrix inversion technique which makes no a priori assumptions about the final shape of the emission spectrum. The absorption of photons in the residual atmosphere, the redistribution of photon energies through Compton interactions and pair-production, and the energy resolution of the detectors were taken into account. The error in this evaluation was estimated to be less than 10%. This photon spectrum is shown in Fig. 2 together with other measurements above 1 keV from the same region of the sky.

Our 2σ upper limits between 20 and 90 keV impose a severe constraint on the data fit at greater energies. In fact, an attempt to fit our data between 90 keV and 19 MeV with a single power-law photon spectrum leads to an estimated flux below 90 keV, a factor of two greater than the corresponding 2σ upper limits and to a reduced $\chi^2 = 2.77$ with 4 degrees of freedom ($\sim 2.5\%$ probability). Therefore, in a power-law representation of our spectral data a break, followed by a steeper spectrum, is needed between 2 and 4 MeV. At lower energies, the best fit is given by

$$I(E) = 7.9 \times 10^{-3} E^{-(1.0 \pm 0.7)}$$
 photons cm⁻² s⁻¹ keV⁻¹

corresponding to a reduced $\chi^2 = 1.45$ with 2 degrees of freedom. At higher energies the slope is about 3.8 if compatibility with the SAS 2 upper limit¹¹ is required.

In principle, we cannot exclude the possibility that the OSO 7 X-ray source 1M0600+46 (ref. 10) might be associated with the Seyfert galaxy MCG8-11-11. On the other hand, the OSO 7 error-box for this source is not available and therefore it is impossible to estimate the probability that the two X-ray sources are associated.

Assuming that we have detected a γ -ray emission from MCG8-11-11 and taking into account that its X-ray flux varies by a factor of 2 to 3 without evident spectral index variation^{2,12}, the HEAO 1 (A2)⁵ and MISO spectra could be in reasonable agreement.

The observed spectral feature at MeV energies is similar to that of the Seyfert galaxy NGC4151, in which a cutoff close to 3 MeV has been indicated by the MISO telescope observation⁶. The existence of the high-energy cutoff in the emission spectrum of these two Seyfert galaxies supports the suggestion¹¹ that a steepening of the spectrum between X-ray and γ -ray energies may be a general characteristic of the active extragalactic objects. This suggestion was based on the comparison between some measured X-ray spectra of active galaxies (for example, MKN501, Cen A, 3C273) and the corresponding positive results or intensity upper limits above 35 MeV.

A model has been recently proposed in which the cutoff at MeV energies is expected to be a 'universal' feature of the emission by active nuclei of galaxies, provided that a rapidly spinning Kerr black hole $(M>10^8\,M_\odot)$ surrounded by a hot $(T\sim10^9\,\text{K})$ accretion disk exists within these nuclei. In these conditions, the Penrose-Compton scattering mechanism¹³ stochastically generates γ -ray bursts with energies up to 3 MeV. The spectral shape is expected to be flatter than the X-ray spectrum in the tens of keV region and the burst duration is about $\Delta T \sim (2.2 \text{ h}) \times 10^{-8} \text{ M/M}_{\odot}$. Since the luminosity of MCG8-11-11 in the energy range 0.09-3 MeV, as obtained from our data, is $L(123 \text{ Mpc}) = 7 \times 10^{46} \text{ erg s}^{-1}$, on the basis of this model a lower limit of $5 \times 10^9 M_{\odot}$ is expected for the mass of the black hole. Thus, the γ -ray burst duration should be greater than 4.6 days, consistent with no evident flux variation during the 6.5 h observation of MCG8-11-11 by the MISO telescope. If we have detected a γ -ray emission from both the Seyfert galaxies NGC4151 and MCG8-11-11 during a balloon flight, the bursts must be rather frequent, at least during some periods of higher activity in these galaxies.

The spectrum of the cosmic γ -ray background⁸ shows a feature at MeV energies similar to that observed from the regions of MCG8-11-11 (Fig. 2) and NGC4151 (ref. 6). Moreover, the γ -ray background has a photon spectral index of about 1.7, not inconsistent within the statistical errors with those

observed at γ -ray energies from these two galaxies. Assuming that the present data pertain to MCG8-11-11, the contribution of Seyfert galaxies to the diffuse γ -ray background in the energy range 0.09-3 MeV can be estimated. The X-ray luminosity function for Seyfert galaxies obtained by the HEAO 1 (A2) experiment leads to a local volume emissivity above L_{Xmin} of 14

$$B_{\rm X}(2-10~{\rm keV}) = 2 \times 10^{38} \left(\frac{L_{\rm Xmin}}{10^{43}}\right)^{-0.75}~{\rm erg~s^{-1}~Mpc^{-3}}$$

Taking a γ -ray background emissivity up to 3 MeV of $B_{\gamma} = 1.8 \times 10^{39} \text{ erg s}^{-1} \text{ Mpc}^{-3}$ (ref. 15), the ratio of the two emissivities is

$$B_{\gamma}/B_{\rm X} = 9(L_{\rm Xmin}/10^{43})^{0.75}$$

Since $L_{\rm Xmin}$ is in the range of (2-5)×10⁴² erg s⁻¹ (refs 14, 16), then

$$B_{\rm y}/B_{\rm X} = 2.7 - 5.4$$

For MCG8-11-11 the ratio between the 0.09-3 MeV γ -ray luminosity and the 2-10 keV X-ray luminosity is:

$$L_{\gamma}/L_{x}(MCG8-11-11) = \frac{7 \times 10^{46} \text{ erg s}^{-1}}{(0.5-1.2) \times 10^{44} \text{ erg s}^{-1}}$$

= $(6-14) \times 10^{2}$

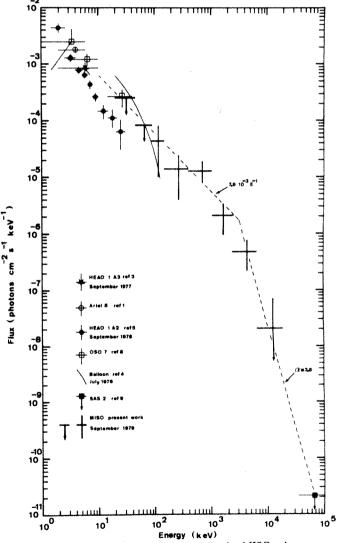

Fig. 2 The photon spectrum observed by the MISO telescope from the region of MCG8-11-11 is shown together with other measurements above 1 keV from the same region of the sky. When available, the date of observation is given. The dashed line represents the best fit power-law of the MISO data with a cutoff at about 3 MeV. The solid curve (ref. 4) represents the fit obtained by the authors assuming a bremstrahlung spectrum.

For NGC4151 the observed γ -ray luminosity is $(0.5-2)\times$ $10^{45} \, erg \, s^{-1}$ (refs 6, 17) and the 2-10 keV X-ray luminosity is in the range $(3.5-7) \times 10^{42}$ erg s⁻¹ (refs 16, 18), giving:

$$L_{\gamma}/L_{\mathbf{X}}(\mathbf{NGC4151}) = (1-5) \times 10^{2}$$

Consequently, we could assume $L_{\gamma}/L_{x} = 10^{2}$ as a characteristic ratio for this sample. The comparison between $L_{\gamma}/L_{\rm X} = 10^2$ and $B_y/B_x = 2.7-5.4$ implies that few per cent of all the Seyfert galaxies with $L_{\rm X}$ (2-10 keV) > $L_{\rm Xmin}$ = (2-5) × 10⁴² erg s⁻¹ could produce the observed diffuse background in the 0.09-3 MeV energy band. And since the y-ray background produced by Seyfert galaxies cannot exceed the total cosmic background, only a few per cent of Seyferts can have y-ray luminosities as high as those observed from NGC4151 and MCG8-11-11.

We thank E. Boldt and D. Leiter for helpful comments and suggestions on this paper.

Evidence for secondary origin of chondrules

Hiroko Nagahara

Geological Institute, University of Tokyo, Hongo, Tokyo 113, Japan

Although chondrules have been extensively studied chemically^{1,2}, petrologically³⁻⁵ and experimentally⁶⁻⁸, their origin is still not certain. I discuss here whether chondrules were condensed directly from the primitive solar nebula9-11 or were formed from precursory materials by various mechanisms, such as high velocity impact of small bodies 12,13, impact on the surface of a parental body^{14,15} or dust fusion¹⁶⁻¹⁸. Investigations of an Antarctic meteorite suggest that chondrules could have formed through melting of pre-existing materials.

The Antarctic meteorite ALH-77015(L3) has closely packed chondrules which show wide variations in texture, bulk chemical composition and mineralogy (work in preparation). They are classified into four textural groups; barred, radial, glassy and porphyritic chondrules. The porphyritic chondrules are most common and show wide variations in their crystal/liquid (groundmass) ratios and crystal shapes. Several chondrules contain two types of olivine. One, which has numerous dusty inclusions and a fuzzy 'dirty' appearance, is always found near the centre of the chondrules as a large anhedral grain, or as disaggregated small anhedral grains (Fig. 1a, b). The other is euhedral small grain which exists around the former olivine and has clear feature. This clear olivine also overgrows the 'dirty' large olivine crystal (Fig. 1 c, d).

These two types of olivine have different chemical compositions. Figure 2a shows the zonal pattern of MgO across the dirty and clear olivines in chondrule 2-4 (Fig. 1d). The dirty olivine shows 'reversal' zoning where the core is more enriched in iron than the rim. In contrast, the clear olivine shows 'normal' zoning

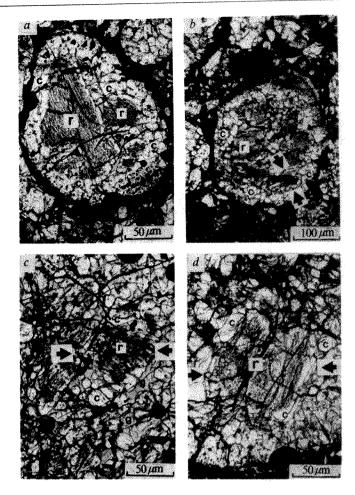

Fig. 1 a, Chondrule 2-1 containing a relic olivine. r, Relic olivine showing large, dirty and anhedral appearance; c, crystallized olivine showing small, clear and euhedral appearance; g, glass. b. Chondrule 2-2. Scanning profile of MgO across the grain between the arrows is shown in Fig. 2b. c, Closed view of relic olivine in chondrule 2-3. Clear part around the relic olivine is overgrown olivine. Scanning profile between the arrows is shown in Fig. 2c. d, Closed view of chondrule 2-4. Scanning profile between the arrows is shown in Fig. 2a.

where the core has more magnesium than the rim. It is impossible to form both types of olivine from a liquid during a single crystallization process. The dirty and relatively iron-rich olivine is probably a relic mineral which was originally rich in iron and was not completely melted when it was heated. On the other hand, the clear olivine seems to have crystallized directly from the liquid, which was probably formed by melting of the preexisting olivine, pyroxene and plagioclase. The fact that the overgrown rim of the relic olivine has the same composition as the clear one (Fig. 2a) supports this hypothesis. Figure 2b, c show the zonal patterns of MgO in the relic olivine with overgrown rim in chondrules 2-2 (Fig. 1b) and 2-3 (Fig. 1c). The overgrown olivine has more magnesium than the relic part, and there is compositional discontinuity between them.

The two types of olivine are also distinguished by their minor element content. Figure 3 shows the CaO content compared with $X_{Mg}(Mg/Mg+Fe)$ of the two olivines in four chondrules. In all cases, crystallized olivine contains more CaO than the relic olivine. In general, the olivine that crystallized at high temperature or that crystallized rapidly contains more CaO (ref. 19). This fact supports the suggestion that the clear olivine is crystallized from the liquid when the chondrules were heated and that the dirty olivine is a relic mineral which had been equilibrated at lower temperatures before chondrule formation.

Relic olivine is the first direct evidence for the presence of precursory material in the formation of chondrules; that is at

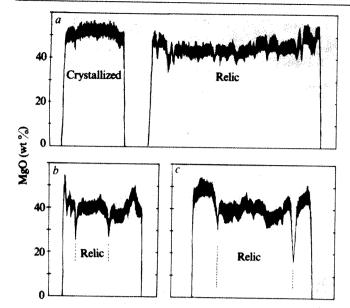

Fig. 2 a, Scanning profile of MgO in crystallized olivine and olivine in chondrule 2-4. Scanning position of relic olivine is shown in Fig. 1d. Chemical composition of rim of the two olivines is equal. b, Chondrule 2-2. Scanning position is shown in Fig. 1b. Overgrown part contains more MgO than the relic part. c, Chondrule 2-3. Scanning position is shown in Fig. 1c.

least some chondrules were not condensed directly from the gas of primitive solar nebula. In the present case, the relic olivine is so large that it can easily be distinguished from the crystallized olivine. However, if the relic olivine were small and/or were nearly completely melted, it would be difficult to distinguish relic minerals from the crystallized ones.

Some chondrules were, therefore, not necessarily crystallized from the completely melted liquid. In this case, the maximum temperature of chondrule formation would be lower than the liquidus temperature of chondrules, which is about 1,300-1,700 °C (ref. 8), and be consistent with recent experimental results (refs 8, 20, and H. N. and A. Tsuchiyama, in preparation). Dodd⁴ has discussed whether the microporphyritic chondrules were formed by fragmentation of rocks which crystallized from liquids and whether they are different in origin from the remelted chondrules such as barred or radial ones. Although his model seems to explain the difference in chondrule

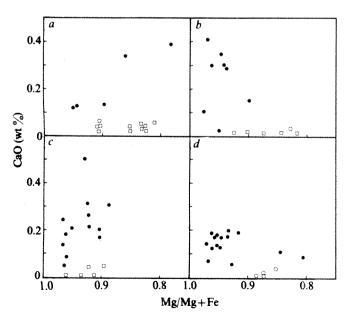

Fig. 3 CaO content in relic (□) and crystallized olivine (●) in four chondrules. a, Chondrule 2-1; b, chondrule 2-2; c, chondrule 2-4; d, chondrule 2-3.

texture, it does not account for microporphyritic texture which is difficult to form from wholly melted materials. The existence of pre-existing materials in the nucleus is an effective explanation for both the formation of porphyritic or microporphyritic minerals (H. N. and A. Tsuchiyama, in preparation). The fact that the bulk composition of the chondrules, which were clearly crystallized from the liquid, are mixture of olivine, pyroxene and plagioclase²¹ also strongly suggests that such chondrules at least were formed by melting of pre-existing materials.

I thank Professor I. Kushiro for discussions and reading the manuscript, also T. Nagata and K. Yanai for providing the sample.

Prebiotic atmospheric oxygen levels

J. H. Carver

Research School of Physical Sciences, Australian National University, Canberra ACT 2600, Australia

It has been argued 1-2 that the early Precambrian atmosphere contained a negligible amount of oxygen and that the transition to the modern oxygen-rich atmosphere began some 2,000 Myr BP when photosynthetic oxygen produced by blue-green algae oxidized ferrous iron in solution and escaped from the ocean to the atmosphere. Others3 have argued for an even earlier occurrence of an oxygen-rich atmosphere. Although photosynthesis has provided the oxygen of the present atmosphere, the photosynthetic model for Precambrian oxygen production has difficulties. There is the problem of identifying the large deposits of reduced carbon needed to account for the red beds4 and the predominant role of photosynthesis as an oxygen source in the early Precambrian has been questioned on both biochemical and geochemical grounds⁵. Before photosynthesis the only possible abiotic source of atmospheric oxygen would have been the direct photodissociation of water vapour by solar UV photons. What atmospheric oxygen level could have been produced by this purely abiotic process? It has been argued⁶ that the abiotic oxygen level was entirely negligible, ≤10⁻¹² PAL (present atmospheric level), but this assumed that the water vapour content of the palaeoatmosphere was the same as at present with a constant H2O mixing ratio of 3.8 p.p.m. above an altitude of 10 km. I argue here that this is too restrictive an assumption and calculate possible atmospheric oxygen levels for larger water vapour mixing ratios which cannot be ruled out by our limited knowledge of Precambrian conditions. Even a moderate oxygen content for the early Precambrian atmosphere could have had significant evolutionary implications because a biologically effective UV ozone screen would be established once the oxygen content exceeded 10⁻² PAL (refs 7-11).

In abiotic conditions the production of free oxygen in excess of atmospheric and surface oxidation would have depended on the amount of water vapour in the lower palaeoatmosphere and on transport processes that governed the escape rate of hydrogen through the exosphere. Abiotic production of atmospheric oxygen is limited by transport rather than by the water vapour photodissociation rate and, provided the exospheric temperature exceeds ~500 K, the hydrogen escape rate is given approximately by the limiting flux condition 12-14

$$\phi = \frac{b}{H} f_{\text{tot}} \tag{1}$$

where b is the binary diffusion parameter, H is the atmospheric scale height and f_{tot} is the total hydrogen mixing ratio at the homopause. Kasting et al. 15 have noted that the limiting flux condition may not apply exactly for palaeoatmospheres having high hydrogen escape rates $(f_{\text{tot}} \ge 10^{-3})$ and low mesospheric oxygen contents $(\le 10^{-5} \text{ PAL})$ owing to the partial ineffectiveness of ion-molecule reactions in converting H_2 into H in the thermosphere. Throughout most of the range of present interest, however, the limiting flux condition should provide a sufficiently good approximation.

For the Earth's atmosphere, $b/H \approx 2 \times 10^{13} \text{ cm}^{-2} \text{ s}^{-1}$ and the present stratospheric water vapour content of ~4 p.p.m. imply a hydrogen escape rate of ~1.6×108 H atoms cm⁻² s⁻¹. This is less than the current hydrogen emission rate from volcanoes estimated⁶ as $V \approx 2.5 \times 10^8 \,\text{H}$ atoms cm⁻² s⁻¹. Thus abiotic processes are now a negligible source of atmospheric oxygen and a net production of oxygen by photodissociation could have occurred in the past only for palaeoatmospheres containing significantly more water vapour than does the present atmosphere. It is unlikely that a highly reducing atmosphere could have survived for long under the photolytic influence of the solar UV radiation and it will be assumed that after an initial period of rapid outgassing the palaeoatmosphere 16 consisted mainly of carbon dioxide, water vapour and nitrogen with a volcanic emission rate comparable to the present value. With these assumptions the net hydrogen escape rate is

 $\psi = \phi - V \approx (2 \times 10^{13} f_{\text{tot}} - 2.5 \times 10^8)$ H atoms cm⁻² s⁻¹ (2) Larger values of f_{tot} imply increased rates of hydrogen escape (and hence oxygen production) but the oxygen level achieved depends on the loss rate. For the assumed palaeoatmosphere that does not contain large quantities of reduced gases the major loss process would be surface oxidation once the hydrogen escape rate exceeded the volcanic emission rate. Oxidation rates in present conditions probably vary as some fractional power of the atmospheric oxygen content¹⁷ because they depend on the rate of exposure of surface materials as well as on the intrinsic properties of those materials. At low oxygen levels in a palaeoatmosphere the supply of oxygen rather than the exposure of fresh material would have been the limiting factor and, following Brinkmann¹⁸, the oxidation rate L is assumed to have been proportional to the oxygen content $n(O_2)$

$$L = \frac{n(O_2)}{\tau} \tag{3}$$

where τ is a characteristic time for surface oxidation. At equilibrium the loss rate L is equal to the oxygen production rate P that corresponds to the net hydrogen escape rate given by equation (2).

The equilibrium atmospheric oxygen levels calculated with P = L are shown in Fig. 1 for $\tau = 0.1-100$ Myr and $f_{\text{tot}} = 10^{-6}-10^{-2}$. Brinkmann¹⁸ investigated Precambrian oxygen production and surface oxidation for a range of τ between 1 and 100 Myr. Hart¹⁹ assumed that τ was ~ 20 Myr. The solid lines in Fig. 1 at τ values of 1 and 10 Myr bracket the present oxidation time estimated by Holland as 3 Myr.

The very dry stratosphere of the present atmosphere^{20,21} is considered to result from circulation and condensation through the cold tropical troposphere with a typical temperature of ~195 K corresponding to a saturated humidity of ~4.5 p.p.m. Because of the approximately exponential dependence of humidity on temperature the water vapour content of the

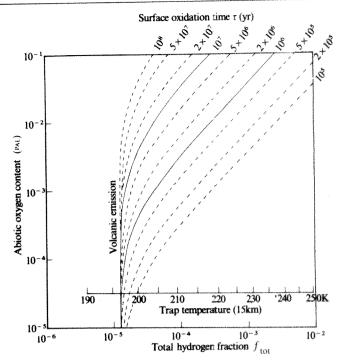

Fig. 1 Equilibrium abiotic oxygen content (PAL) as a function of surface oxidation time $(\tau \, \text{yr})$ and total hydrogen content (f_{tot}) in the lower atmosphere. Temperatures that would produce a water vapour content equal to f_{tot} for a notional cold trap at 15 km are indicated. The solid lines bracket estimates of the present surface oxidation time constant. Note that the atmospheric oxygen content is negligible unless f_{tot} exceeds its present value so that exospheric hydrogen escape overwhelms volcanic hydrogen input.

stratosphere would vary rapidly with changes in the temperature of the atmospheric cold trap. If, for example, the polar tropopause at ~ 225 K were the controlling temperature the stratospheric water vapour content would increase by nearly two orders of magnitude. Figure 1 also shows notional 'trap temperatures' corresponding to particular values of $f_{\rm tot}$ even though the palaeoatmosphere may not have had a true tropopause.

It is unlikely that the palaeoatmosphere would have possessed the particular combination of temperature profile and circulation pattern that produces the very dry stratosphere of the present atmosphere. That substantial changes in the radiation balance of the atmosphere have occurred during geological time is implied by the fact that the Earth's surface temperature has remained within the range 0-100 °C (as indicated by geological evidence for the continued presence of large amounts of liquid water) even though theories of stellar evolution imply that the Sun has brightened²² by 30-40% since it first joined the main sequence some 4,500 Myr ago. Sagan and Mullen²³ suggested that an ammonia greenhouse might have kept the Earth's mean surface temperature above the freezing point of seawater but it is unlikely that an ammonia-rich atmosphere could have persisted throughout the early Precambrian and a more probable explanation is that the greenhouse effect was provided by a CO₂ rich palaeoatmosphere^{24,25}. Other possible explanations for the non-freezing of the oceans under the weak early Sun are changes in the albedo or the rotation rate of the Earth²⁶. Any such explanation would profoundly affect the temperature profile and water vapour content of the palaeoatmosphere.

The range of total hydrogen contents, $f_{\rm tot}$, shown in Fig. 1 corresponds to notional cold trap temperatures at 15 km between 190 and 250 K. Figure 1 only indicates a range of possibilities for the equilibrium abiotic oxygen content of a palaeoatmosphere and any conclusions based on our meagre understanding of the Precambrian environment must be very tentative. The available evidence does, however, suggest that the Precambrian lower atmosphere may have been warmer and moister than at present so that significant quantities of atmos-

pheric oxygen could have been produced by abiotic means. Surface temperatures as high as 52 °C (325 K) at 1,300 Myr BP and 70 °C (343 K) at 3,000 Myr BP are suggested by the chert measurements of Knauth and Epstein²⁷. Schopf²⁸ has summarized evidence indicating Precambrian ocean surface temperatures of 50-70 °C. Model atmosphere calculations^{24,25} also suggest that early Precambrian surface temperatures may have been warmer than at present owing to the atmospheric greenhouse effect provided by a dense carbon dioxide blanket. For oxygen deficient atmospheres the photochemical region extends well down into the lower atmosphere with the water vapour photolysis rate being a maximum at an altitude of \sim 5 km (ref. 6). The hydrogen escape rate in the limiting flux condition is set by the water vapour content at the 10-15 km level and above ~20 km hydrogen molecules replace water vapour as the dominant hydrogen species. Even if the atmosphere is very cold above 20 km it will not affect the water vapour level that fixes the limiting flux.

Model atmosphere calculations suggest significant warming of the lower atmosphere in Precambrian conditions. The Precambrian models of Morss and Kuhn²⁹ indicate temperatures ~15 °C warmer than at present at 15 km which would imply $f_{\text{tot}} \sim 10^{-4}$ and $n(O_2) \sim 10^{-2}$ for present day surface oxidation rates and $n(O_2) \sim 10^{-3}$ for 10 times the present oxidation rate. These models, however, neglect variations in solar luminosity and more detailed calculations of palaeotemperature profiles are required before any very firm conclusions can be drawn from the models. Larger values of $n(O_2)$ are implied by the chert measurements of Knauth and Epstein²⁷ which indicate a possible surface warming of (40-50 °C). If this warming had extended throughout the lower palaeoatmosphere (if the lapse rate had been similar to the present one) the chert temperatures would imply total hydrogen fractions f_{tot} at 15 km in the range 10^{-3} 10⁻². In these conditions equilibrium abiotic oxygen levels $n(O_2)$ could have reached 0.1 PAL unless surface oxidation rates were substantially greater than at present. Thus if the temperatures were as high as suggested by the model atmosphere calculations and by the chert measurements abiotic atmosphere oxygen levels could have approached 10⁻³ PAL (even for a surface oxidation rate 10 times the present) and may have reached 10^{-2} -0.1 PAL during any particularly warm and moist Precambrian conditions. Atmospheric oxygen in such amounts would have been sufficient to have produced a biologically effective Precambrian ozone shield⁷⁻¹¹. The present calculations are consistent with the geological results of Grandstaff³⁰ who has shown that the occurrence of detrital uraninite does not require an essentially anoxic early Precambrian atmosphere.

Surface viscosity of water

J. C. Earnshaw

Department of Pure and Applied Physics, The Queen's University of Belfast, Belfast BT7 1NN, UK

The recent suggestion that surface viscosity effects can arise from the molecularly diffuse nature of a fluid surface or interface has prompted this re-examination of data concerning capillary waves on the surface of water. Previous work2 has shown that the propagation of such waves is not compatible with the predictions of accepted theory for a surface having no abnormal rheological properties. These apparent discrepancies can be resolved in terms of one of the surface shear viscosities predicted by Goodrich. The existence of such surface viscosities for pure water suggests that caution must be exercised in interpreting surface viscosities observed for surface films in terms of molecular structure of, or interactions within the films.

Capillary waves on a fluid interface propagate in a manner governed by the viscoelastic properties of the system. The evolution of the waves in time can be described (in two dimensions; x in the surface) by a vertical displacement

$$\zeta = \zeta_0 \cos(qx) \exp(\alpha t) \tag{1}$$

where q is the surface wave-vector $(2\pi/\lambda)$ and α is a complex frequency:

$$\alpha = i\omega - \Gamma \tag{2}$$

In the case of clean liquid-air surface there is a well-established dispersion equation³ (based on linearized hydrodynamic theory) relating α to q and to the physical properties of the fluid. In first-order approximation this predicts a frequency

$$\omega^2 = \sigma_0 q^3 / \rho \tag{3}$$

and the damping constant

$$\Gamma = 2\eta_0 q^2 p \tag{4}$$

where σ_0 and η_0 are respectively the surface tension and the dynamic viscosity of the liquid. Non-propagating surface modes exist for sufficiently large q; they are not of present concern. Higher-order approximations for ω and Γ can be derived; they essentially agree with exact numerical solutions of the dispersion equation^{2,4}. Careful experiments² on thermally excited capillary waves of small amplitude on a water-air interface do not agree precisely with this theory. The observations imply a viscosity η_0 rather above the accepted value for water. Modification of the dispersion equation to allow for the viscosity of air5 only partially removes these systematic discrepancies. It has not been clear to date whether the discrepancies arise from the linearization of the hydrodynamic equations or from some modification of the properties of water close to the surface. Persuasive arguments can be presented against the former possibility.

Recently Goodrich has shown that the molecularly diffuse interfacial region between two fluids displays anisotropic momentum transport parallel to and normal to the interface; this anisotropy leads to surface viscosity effects. Goodrich identifies four surface viscosity effects, two (κ and κ_N) describing dilational viscosity within and normal to the interface and two $(\eta \text{ and } \eta_N)$ describing shear viscosity. These surface viscosity coefficients are usually associated with the viscoelastic behaviour of a fluid interface supporting a surfactant monolayer.

There seems, however, to be no a priori reason why such effects should not arise for clean fluid surfaces or interfaces. Goodrich's theory thus justifies an examination of the second possible explanation mentioned above.

Surface viscosity effects due to surfactant monolayers exert well-understood effects on capillary waves3. The predominant effect of the additional viscous dissipation is to increase the effective damping of the waves. Goodrich 1.6 shows that κ_N has no part in the linearized theory of capillary waves; further the shear modes decouple from the other modes and are not observed in the experiments mentioned above (these involve the scattering of light, which does not couple to surface shear modes). The hydrodynamic theory is generalized by introducing frequency dependence to the surface tension:

$$\sigma(\omega) = \sigma_0 + i\omega \eta_N \tag{5}$$

and a frequency dependent surface compressibility:

$$\varepsilon(\omega) = \varepsilon_0 + i\omega\kappa \tag{6}$$

Classically ε_0 , κ and η_N are all zero for clean surfaces but may assume non-zero values in the presence of a surface film. The spectrum of light scattered by surface waves reflects their temporal evolution (experiments directly yield values for ω and Γ); the theoretical form including surface viscosity effects has been calculated7 and can be used to estimate the viscoelastic properties of interfaces.

The effects of κ and η_N on ω and Γ are shown in Fig. 1; the two coefficients are seen to have very different effects. The increase in Γ caused by κ seems to saturate, whereas that due to η_N increases until eventually the capillary waves become overdamped. These effects of η_N are similar to those of an increased value of bulk viscosity, η_0 . The various surface viscosities have quite different effects on the dispersion properties of surface waves. Figure 2 shows that the relative effect of κ on Γ is approximately independent of q whilst that due to η_N increases with q. The effects of κ and η_N are comparatively small and rather large values were chosen for Fig. 2 to accentuate the general trends. The differences in behaviour of ω with q, if plotted on Fig. 2, would not be distinguishable (except for the higher η_N value at $q > 1,500 \text{ cm}^{-1}$).

Also shown in Fig. 2 are data² on Γ for waves on clean water-air surfaces; the data deviate increasingly from the classical assumptions ($\varepsilon_0 = 0$, $\kappa = \eta_N = 0$) as q increases. The wave frequencies are uniformly close to those for the classical

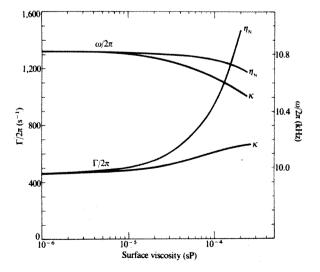

Fig. 1 The effects of surface viscosity $(\eta_N \text{ and } \kappa)$ on the frequency and damping constant of capillary waves $(q = 400 \text{ cm}^{-1})$ Note the different scales for ω and for Γ .

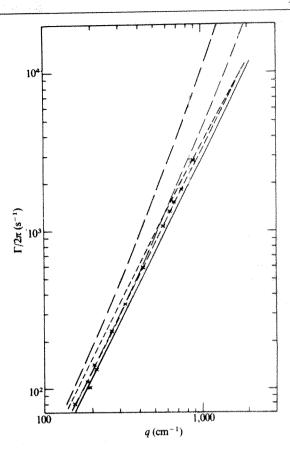

Fig. 2 The variation of Γ with q for water under various assumptions about the surface: —, classical surface, $\kappa = \eta_N = 0$; ———, $\eta_N = 0$ and $\kappa = 2 \times 10^{-5}$ sP (lower line) and 10^{-4} sP; ———, $\kappa = 0$ and $\eta_N = 2 \times 10^{-5}$ sP (lower line) and 10^{-4} sP. Also shown are the data of ref. 2 for water at 20 °C.

assumptions2. Taking as minimal assumptions the accepted values $\sigma_0 = 72.75$ dyne cm⁻¹ and $\eta_0 = 1.002$ cP (appropriate to T = 20 °C) and $\varepsilon_0 = 0$ dyne cm⁻¹, values for κ and η_N can be estimated using these data. The overall maximum likelihood estimates are $\kappa = 0$ sP (surface Poise—mN m⁻¹ s) and $\eta_N = 1.2$ $(\pm 0.4) \times 10^{-5}$ sP. The upper limit on κ is 1.5×10^{-5} sP. The limits quoted in both cases are 95% confidence limits.

Unfortunately quantitative data for comparison with that of ref. 2 is scarce. Several studies of capillary waves on water have used similar experimental techniques to those of ref. 2. The tabulated data of Langevin⁸ are all compatible with the present conclusions apart from the lowest q value investigated, for which the instrumental correction to Γ is largest. Bird and Hills derive a bulk viscosity slightly above the accepted value. The data of Hård et al. 10 yield estimates of η_0 below the accepted value; in this study, however, instrumental corrections were only made approximately and may have been overestimated. The damping of mechanically generated capillary waves on water seems to be consistent with the present conclusions.

Raman investigation of ring configurations in vitreous silica

Shiv K. Sharma

Hawaii Institute of Geophysics, University of Hawaii, Honolulu, Hawaii 96822, USA

Joseph F. Mammone* & Malcolm F. Nicol

Department of Chemistry, University of California, Los Angeles, California 90024, USA

Random network models of glass structures1 provide satisfactory qualitative descriptions of many properties of glasses (see reviews in refs 2-4). However, to obtain good quantitative agreement between theoretical analyses and experimental observations⁵⁻¹¹ it is often necessary to assume that specific ring structures in the random networks have special importance. In the case of vitreous silica (v-SiO₂), distributions of loops of SiO₄ tetrahedra in the random network have been invoked⁵ match calculated and experimental X-ray radial distribution functions (RDF). High resolution X-ray photoelectron spectra¹² of v-SiO₂ and quartz also provide evidence for the occurrence of four-, six- and higher-membered rings of SiO4 tetrahedra in v-SiO2. Raman spectra are also sensitive to local microstructures in vitreous solids. We have therefore examined the question of rings in the structure of v-SiO2 by comparing its Raman spectrum with spectra of crystalline silica polymorphs whose shortest loops contain four (coesite) and six (for example, α -quartz) tetrahedra. This comparison indicates that the sharp shoulder at 490 cm⁻¹ in the spectrum of v-SiO₂, previously attributed to a defect structure3 or a longitudinal optic mode14 can be assigned to four-membered ring structure. We discuss here possible basis for the stability of four-membered rings of SiO₄ tetrahedra in v-SiO₂ at ambient pressure. Possible reasons for the absence of the 490 cm⁻¹ band in the vibrational densityof-states derived for a random network model by Bell and co-workers 12,15 are discussed.

Figure 1 shows first-order room-temperature Raman spectra of polycrystalline samples of α -quartz and coesite and a bulk sample of high purity v-SiO₂. These spectra were measured in the 90° scattering configuration with a Jobin-Yvon Raman spectrometer and 488-nm line of an argon ion laser¹⁶. The positions and spectral characteristics of the bands in these spectra are given in Table 1. Examination of these spectra suggests that the very strong band at 437 cm⁻¹ and the sharp shoulder at 490 cm⁻¹ in the spectrum of v-SiO₂ are related to the strong bands at 465 and 521 cm⁻¹ in the spectra of α -quartz and coesite, respectively (Table 1).

Theoretical analyses 17-20 of the vibrational spectrum of v- SiO_2 have indicated that the 437 cm⁻¹ band belongs to $\nu_s(Si-O-$ Si), the symmetric stretch. In this mode, the bridging oxygen moves along the line bisecting the Si-O-Si bond angle. The frequency of this mode is sensitive to both the Si-O-Si bond angle and the Si-O band length 18,19. A third parameter which could affect $\nu_s(Si-O-Si)$ is the short-range connectivity of the network structure. Raman data for framework aluminosilicates with four-, five- and six-membered rings of TO₄ tetrahedra (T = Si or Al) indicate that, among crystals of isochemical compositions, the frequency of $\nu_s(T-O-T)$ increases with reduction in the ring size (Table 2). This correlation implies that the band at 437 and the shoulder at 490 cm⁻¹ in v-SiO₂ arise from tetrahedral network structures, composed of six- and four-membered rings, respectively. That these bands occur at lower frequencies in the spectrum of v-SiO2 than in the spectra of the crystalline polymorphs is probably due to differences in Si-O-Si bond angles in the rings in v-SiO2 and the crystalline

polymorphs. Raman measurements of α -quartz under high pressures have shown that the frequency of the $464~\text{cm}^{-1}$ band is sensitive to compression²⁶. Studies of neutron irradiated v-SiO₂ also show that the frequencies of these bands increase on densification of the vitreous silica²⁷.

The large halfwidth of the 437 cm⁻¹ band of v-SiO₂ (Fig. 1) is usually attributed to the dispersion of Si–O-Si angles. However, the position of ν_s (Si–O-Si) also depends strongly on ring size (see Table 2). Thus, the ν_s (Si–O-Si) vibrational modes of five-, seven- and higher-membered rings of SiO₄ tetrahedra, which may also be present in the random network, may be responsible for the broadening of the 437 cm⁻¹ band.

The v-SiO₂ band at 606 cm⁻¹, which has been attributed to defects ^{13,27}, has no counterpart in the spectra of silica polymorphs (Fig. 1). Our data, therefore, support its assignment to defect structures involving partially broken Si-O bonds in the network²⁸.

The 400–600 cm⁻¹ region of the Raman spectrum of v-SiO₂ thus suggests that at least three different types of structural configurations occur in v-SiO₂. Each of these configurations, of course, will be associated with a range of Si–O–Si bond angles such that the material lacks long range order. The broad and complex bands in the $700-1,200 \, \mathrm{cm}^{-1}$ region of the v-SiO₂ spectrum (Fig. 1) also may be attributed to the presence of at least three different types of structural groups in metastable equilibrium in v-SiO₂.

The presence of three different types of structural groups in $v\text{-SiO}_2$ can be further supported by the density and Raman data²⁷ on neutron irradiated $v\text{-SiO}_2$. Both the density and intensity of the 490 cm⁻¹ band of $v\text{-SiO}_2$ increase on exposure to neutrons, and both properties show maxima at 5×10^{19} neutrons cm⁻². Neutron irradiation increases the intensity of the 606 cm^{-1} band at an even faster rate than the intensity of the 490 cm^{-1} band, but the 606 cm^{-1} intensity does not show a maximum. In contrast, the intensity of the 437 cm^{-1} band of unirradiated SiO_2 decreases with increasing exposure to neutrons²⁷. The different responses of the 437, 490 and 606 cm^{-1}

bands of v-SiO₂ to neutron irradiation clearly demonstrate that these bands belong to different species. The observed maxima in the intensity of the 490 cm⁻¹ band and in the density at 5×10^{19} neutrons cm⁻² can be attributed to the conversion of the five-, six- and higher-membered rings of SiO4 tetrahedra into fourmembered rings.

Recently, Mikkelsen and Galeener²⁹ reported that both the density and the intensity of the 606 cm⁻¹ band of v-SiO₂ (Suprasil W1) increase with the fictive temperature. The intensity of the 490 cm⁻¹ band was also enhanced as the fictive temperature of v-SiO2 increased (see Fig. 1 in ref. 29), although the magnitude of the increase could not be precisely determined.

The increase of the intensity of the 606 cm⁻¹ band with increasing fictive density suggests either that a higher density structure is responsible for the 606 cm⁻¹ mode, or that, while most of the network relaxes to a denser than average structure, this is accompanied by an increase in the concentration of a less dense structure responsible for the 606 cm⁻¹ band²⁹. The Raman data²⁷ on neutron-irradiated v-SiO₂ clearly show that the 606 cm⁻¹ band belongs to a less dense structure. At exposures of 2×10²² neutrons cm⁻², the intensity of the 606 cm⁻¹ band is 1.4 times that for v-SiO₂ exposed to only 5×10^{19} neutrons cm⁻²; but the additional irradiation decreases the density to 2.518 g cm^{-3} from 2.560 g cm^{-3} .

The intensities of the 490 and 606 cm⁻¹ bands increase with increasing fictive density as well as with increasing density of v-SiO₂ at low neutron irradiation (≤5×10¹⁹ neutrons cm⁻²); this suggests that there is a relationship between the fourmembered ring structure responsible for the 490 cm⁻¹ band and the defect centres responsible for the 606 cm⁻¹ mode. The silicon atoms at these defects carry a formal positive charge. We suggest that the four-membered rings in v-SiO2 at ambient pressure are stabilized by the excess positive charge on silicon atoms at the defect sites just as the four-membered rings of TO4 tetrahedra in crystalline feldspar are stabilized by cations³⁰. This interpretation suggests that the intensities of both the 490 and 606 cm⁻¹ bands will initially increase with the density of v-SiO₂ at ambient pressure. However, the extent to which defect centres can stabilize four-membered rings at ambient pressure is limited as indicated by the maxima in both the intensity of the 490 cm⁻¹ band and the density of unirradiated v-SiO₂ at an

exposure of 5×10^{19} neutrons cm⁻². Bell et al. 15 and Bell and Dean 17,31 have computed vibrational densities-of-states and other properties of SiO₂ for large (~200 SiO₄ molecular unit) continuous random-network clusters of almost perfectly tetrahedral units. Within each cluster, molecular units interact through short range (nearest-neighbour) bond forces while the cluster interacts with non-bridging oxygens at its surface. Raman spectra of v-SiO₂ have recently been computed¹¹ in terms of the behaviour of much smaller sections (typically 10-20 molecular units) of Bell and Dean's clusters. Computations with these models have given fairly good

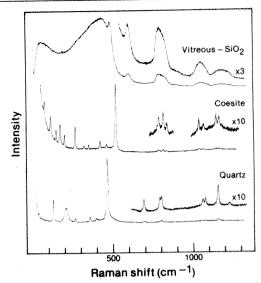

Fig. 1 Raman spectra of crystalline α -quartz, coesite and vitreous silica (v-SiO₂) at room temperature (laser 488.0 nm; slit and laser power at the sample used for crystalline polymorphs were 3 cm and 300 mW and for SiO₂ glass these were 5 cm⁻¹ and 500 mW, respectively).

agreement with observed X-ray and neutron diffraction data. Calculated spectra also resemble, to a first approximation, observed Raman spectra of v-SiO2. However, the sharp bands at 490 and 606 cm⁻¹ and the broad band at 1,200 cm⁻¹ do not have counterparts in the computed spectra ^{14,32}. This discrepancy may result from two factors that the v-SiO2 models of Bell and co-workers do not take into account: (1) the presence of defect centres involving partially broken Si-O bonds²⁸ in the interior of v-SiO₂ and (2) the ring statistics, especially the presence of four-membered ring structures which seem to be stabilized by the defect centres. It is now possible to calculate vibrational spectra of vitreous solids on the basis of random network models containing defect centres 10,33 and ring structures 10,11. The present results suggest that such calculations for v-SiO2 should be attempted to extend our understanding of the Raman spectrum as well as the structure of vitreous silica.

Most oceanic volcanic centres caused by hotspot activity are surrounded by sea floor that is unusually shallow for its age^{1,2}. There is increasing evidence that swells found on older sea floor, like the Hawaiian Swell, have formed from a broad-scale reheating and thinning of the lithosphere as it passes over a mantle hotspot^{3,4}. If the formation and subsequent disappearance of these swells are controlled by thermal processes, they should have an above-normal heat flux. We present here the results from 95 new heat flow measurements on the Hawaiian Swell. Along the older part of the swell the heat flow is 20–25% higher than the normal heat flow for crust of this age. This anomaly is consistent with the observed swell uplift. The shape and amplitude of the heat flow anomaly require that the reheating be largely confined to the lower half of the lithosphere.

The Hawaiian Swell is a broad, elongate region of anomalously shallow depths surrounding the youngest portion of the Hawaiian–Emperor seamount chain (Fig. 1). The swell has a maximum width of $\sim 1,200\,\mathrm{km}$ and extends more than 2,700 km WNW along the length of the Hawaiian chain. Southeast of Oahu the swell rises $\sim 1.5\,\mathrm{km}$ above the surrounding sea floor. The height of the swell gradually decreases to the northwest along the older portion of the island chain. While various models have been proposed for the origin of the Hawaiian Swell⁵⁻⁷ it has also been argued^{3,4} that the swell forms as a result of a broad-scale reheating of the lithosphere by the Hawaiian hotspot. The main evidence for this model is that the disappearance of the swell seems to follow a predictable thermal

subsidence curve³. If the lithosphere has been reheated, the swell should have an above-normal heat flux with the size and location of the heat flow anomaly depending on the manner in which the lithosphere is reheated⁴.

To test this hypothesis we recently obtained 95 reliable heat flow measurements at eight well-sedimented sites along the Hawaiian Swell (Fig. 1)⁸. The measurements were made with the Woods Hole Oceanographic Institution's digital heat flow instrument using thermistors externally mounted on either a piston core or a multipenetration pogo probe. Thermal conductivity measurements using the needle probe method⁹ were made on sediment samples recovered in piston cores at each site and a single mean conductivity determined for each area. The mean heat flow at each site, weighted according to the errors in individual heat flow measurements, is given in Table 1 and compared with the normal heat flow expected for crust of this age in Fig. 2.

The heat flow measurements at each site are remarkably uniform. The 95% confidence limits on the weighted site means are $<\pm4$ mW m⁻² (0.1 h.f.u.) at all but one site. The nearnormal heat flow on the youngest part of the swell precludes any significant reheating of the upper part of the lithosphere. However, the gradual increase in heat flow over the older part of the swell is consistent with reheating of the lower part of the lithosphere as it will take several million years for these relatively deep temperature changes to diffuse upwards. While part of the increase in heat flow between sites C and E is attributable to the \sim 10 Myr age offset across the Molokai fracture zone (Fig. 1), the heat flow at sites F, G and H is still 7-12 mW m⁻² higher than the expected heat flow for crust of this age. This anomaly, which is \sim 20-25% of the normal background heat flux, is clearly resolvable with the present data.

To determine if this heat flow anomaly is consistent with the amount of reheating required to uplift the swell, the expected heat flow for a simple reheating model has been calculated. The reheating process is assumed to begin at the lithosphere's base and proceed upwards, raising all lithospheric temperatures below a depth L to $T_{\rm m}$, the assumed temperature of the asthenosphere. The initial temperature above depth L remains unchanged. While other forms of reheating are possible, this model puts the added heat as deep as possible and satisfies the constraint that no large heat flow anomaly is associated with the youngest part of the swell. In this model, the sea floor depth and heat flow at any point along the swell are completely determined by the geotherm (age) of the lithosphere when reheated, the initial height of the swell and the time since reheating8. If we assume an age of 90 Myr for the lithosphere around Hawaii and a plate model geotherm for the lithosphere 10, then lithospheric thicknesses after reheating of 37-45 km are required to explain the observed swell uplift (corrected for the isostatic loading of

N, number of gradient measurements. \vec{K} , mean site thermal conductivity (corrected to in situ conditions). \vec{Q} , weighted mean heat flow with sample standard deviation s.d. t_c, Estimated crustal age. t_H, Inferred time since reheating. Crustal ages were estimated using the isochron map in ref. 12. Time since reheating was determined by projecting the site locations onto a line joining Hawaii and Midway and assuming an age of 27 Myr for Midway

100-200 m of sediment). These lithospheric thicknesses are about half the normal thickness of lithosphere of this age.

The predicted subsidence and anomalous heat flow for this range of values are shown in Fig. 3. The upper subsidence curve (L = 37 km) matches the data around Hawaii reasonably well, but seems too shallow over most of the rest of the swell. Inspection of the detailed bathymetry around the Hawaiian Islands¹¹ shows that there are two high spots on the swell, at 3 and 17 Myr, where smaller island chains (fracture zones?) crosscut the swell. Thus, the depths in these two areas may be anomalously shallow. The lower subsidence curve (L = 45 km) is a better fit over most of the swell. The heat flow anomaly observed on the swell also seems to be closer to the anomaly predicted by this lower subsidence curve, although the heat flow at the three oldest sites is less than predicted. This part of the swell actually formed when the hotspot was reheating slightly younger lithosphere (~80-Myr old) before it crossed the Molokai fracture zone (Fig. 1). When this is considered (dashed line in Fig. 3), the heat flow anomaly on this part of the Hawaiian Swell is probably large enough to be consistent with the observed swell uplift.

The main uncertainty in the present study is that reliable measurements of heat flow were not obtained on crust of the same age located off the swell, so the observed heat flow anomaly cannot easily be separated from any regional anomaly unrelated to the swell. The size of the observed anomaly is also small and close to the resolution of the data. Thus, although the

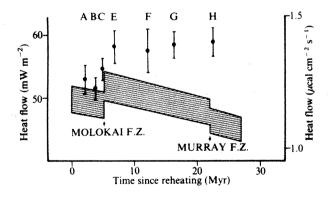

Fig. 2 Observed heat flow on the Hawaiian Swell with 95% confidence limits plotted against the time since each site passed over the Hawaiian hotspot. The shaded band is the normal heat flow expected for crust of this age estimated using a simple $(age)^{-1/2}$ relation with a scale factor of 11-12 h.f.u. (ref. 10). Assumed crustal ages and reheating times are given in Table 1. Site D was omitted from this plot because the heat flow is poorly determined (only four measurements) and the site is probably located on the Molokai fracture zone.

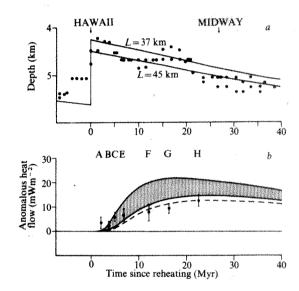

Fig. 3 a, Observed and predicted swell subsidence. Dots are 1° × 1° averages of the depth of the crest of the Hawaiian Swell along the lines shown in Fig. 1. Solid curves are predicted subsidence for reheating model where L is the lithospheric thickness after reheating. b, Anomalous heat flow observed on the Hawaiian Swell compared with predicted heat flow for L = 37 km (upper solid curve) and L = 45 km (lower solid curve) assuming an age of 90 Myr before reheating. These curves represent the upper and lower bounds on the heat flow anomaly required to explain the observed swell uplift. The dashed line shows the effect on the lower bound of reheating 80-Myr old rather than 90-Myr lithosphere (see text for discussion).

present measurements are consistent with lithospheric reheating, the strongest evidence for this model remains the manner in which the swell subsides.

This work was sponsored by NSF grant OCE79-19226 to the Woods Hole Oceanographic Institution. We thank Barry Parsons for helpful comments.

Charnockite geobarometers based on coexisting garnet-pyroxene-plagioclase-quartz

D. Perkins III & R. C. Newton

Department of the Geophysical Sciences, University of Chicago, Chicago, Illinois 60637, USA

Numerous geothermometers based on compositions of coexisting minerals have been calibrated experimentally or theoretically during the past 10 yr. In contrast, few continuous-reaction geobarometers exist which have had wide application. One, based on the reaction of cordierite to garnet, sillimanite and quartz, is limited by a relatively narrow pressure range of application and also by conflicting calibrations^{1,2} because the mixing relations of Mg and Fe and the role of H2O in cordierite3 are not understood. Another successful barometer uses the assemblage garnet, plagiociase, Al₂SiO₅ and quartz^{4,5} Continuous geobarometers based on the reaction of orthoferrosilite to fayalite plus quartz⁶ and on the aluminium content of enstatite in equilibrium with garnet have been used to a lesser extent. The former barometer is limited by rarity of the requisite assemblage, and the latter by uncertain experimental calibration for crustal rocks. We calibrate here two mineralogical geobarometers from measured thermodynamic data. The participating minerals, pyroxenes, garnet, plagioclase and quartz, are frequently associated in high-grade metamorphic rocks. Calculation of pressures for several terrains show that the geobarometers yield reasonable and consistent results for the entire range of crustal pressures.

Most high-grade metamorphic terrains are in Precambrian shield areas and are dominated by orthopyroxene-bearing (charnockitic) acid to intermediate gneisses which invariably contain abundant basic segregations and lenses (basic granulites). The assemblage pyroxene-plagioclase-quartz is essential to charnockitic rocks, and garnet is present in many, including the type Madras charnockite occurrence. Garnet-pyroxene-plagioclase, frequently with quartz, is also characteristic of the basic units in many terrains. The four phase assemblages are represented by the reactions:

$$\begin{aligned} CaAl_2Si_2O_8 + Mg_2Si_2O_6 &= 1/3Ca_3Al_2Si_3O_{12}\\ &\text{anorthite} \end{aligned} \\ &+ 2/3Mg_3Al_2Si_3O_{12} + SiO_2\\ &\text{pyrope} \end{aligned} \tag{1}$$

$$\begin{array}{l} CaAl_2Si_2O_8 + CaMgSi_2O_6 = 2/3Ca_3Al_2Si_3O_{12} \\ \text{anorthite} & \text{diopside} \end{array}$$

$$+1/3Mg_3Al_2Si_3O_{12}+SiO_2$$
 (2)

Because these reactions have large volume changes they are suitable for geobarometry. The reactions are of high variance in rocks: plagioclase contains large amounts of NaAlSi₃O₈ (albite) in solid solution; the garnets and pyroxenes of granulites are complex, containing major amounts of Fe and smaller amounts of other elements. Previous attempts to calibrate these barometers^{9,10} have used experimental syntheses of the fourphase assemblages in simple systems^{11,12}, but long extrapolations are necessary from experimental temperatures and compositions of the phases were not reversed. An earlier thermodynamic calibration of reaction (1) was hampered by incomplete data for the phases¹³. Data are now complete enough for relatively rigorous formulations of the geobarometers from thermodynamic measurements.

The equilibrium condition that the Gibbs energy change is zero for reaction (1) at given temperature, T, and pressure, P, of metamorphism leads to the following expression:

$$-\Delta H^{\circ} + T\Delta S^{\circ} \cong RT \ln \frac{(\alpha_{Mg}^{Gt})^{2} \cdot (\alpha_{Ca}^{Gt})}{\alpha_{En}^{Opx} \cdot \alpha_{An}^{Pl}} + P\Delta V^{\circ}$$
(3)

where ΔH° and ΔS° are, respectively, the enthalpy and entropy changes of the reaction, ΔV° the molar volume change at T, and the α s denote the activities of MgAl_{2/3}SiO₄ and CaAl_{2/3}SiO₄ in garnet, Mg₂Si₂O₆ in orthopyroxene and CaAl₂Si₂O₈ in plagioclase. The approximation sign is used because of neglect of differential compressibilities and expansivities. A similar equilibrium condition is obtained for reaction (2).

Several recent thermochemical measurements allow evaluation of the left-hand side of equation (3), the standard Gibbs energy change, with moderate accuracy, thus avoiding the uncertain derivation from phase equilibrium studies. Enthalpy of solution measurements at 970 K for enstatite and pyrope diopside and grossular and anorthite give ΔH° as the difference in enthalpies of formation from the oxides. Low temperature adiabatic heat capacity measurements and high temperature heat content measurements, give ΔS° (refs 17–19). An entropy increment of 1.0 cal K⁻¹ is added to anorthite to account for Al, Si disorder 0.0 Over a temperature range of a few hundred degrees centred around 970 K, ΔH° and ΔS° are virtually constant.

The activities of Ca-Mg-Fe garnet components can be referred to constant W parameters for the bounding binary joins, such that the activity coefficient of MgAl_{2/3}SiO₄, $\gamma_{py} = \alpha_{py}/X_{py}$ is given by:

$$Rt \ln \gamma_{\text{py}} \cong W_{\text{MgFe}} X_{\text{Fe}}^2 + W_{\text{MgCa}} X_{\text{Ca}}^2 + (W_{\text{MgFe}} + W_{\text{MgCa}} - W_{\text{CaFe}}) X_{\text{Ca}} X_{\text{Fe}}$$
(4)

with a similar expression for $\gamma_{\rm gr}$ (ref. 21). $W_{\rm MgCa}$ has been measured calorimetrically and, for the ranges of compositions considered here, is, to a good approximation, $W_{\rm MgCa}$ (cal) = $3,300-1.5\,T$ (K)⁴. The simplest values of $W_{\rm CaFe}$ and $W_{\rm MgFe}$ compatible with high temperature and high pressure phase equilibrium measurements are zero^{22,23}. The unknown mixing properties of Mn in garnets restricts consideration to garnets with Mn \leq Mg/3. Enthalpy of solution studies on plagioclase¹⁶ lead to the 'Al-avoidance' activity model, expressed by

$$\alpha_{\rm an} = \gamma_{\rm an} \frac{X_{\rm an} (1 + X_{\rm an})^2}{4}$$

$$RT \ln \gamma_{\rm an} = (1 - X_{\rm an})^2 (2,075 + 9,318 X_{\rm an})$$
 (5)

Finally, the Mg₂Si₂O₆ and CaMgSi₂O₆ activities in pyroxene are taken as 'ideal two-site'

$$\alpha_{\text{en}}^{\text{Opx}} = X_{\text{Mg}}^{\text{M2}} \cdot X_{\text{Mg}}^{\text{M1}}$$

$$\alpha_{\text{di}}^{\text{Cpx}} = X_{\text{Ca}}^{\text{C2}} \cdot X_{\text{Mg}}^{\text{M1}}$$
(6)

where M1 and M2 are the pyroxene structural sites for nontetrahedral cations. Following Wood and Banno²⁴, Al^{VI}, Cr, Ti and Fe³⁺ are ordered in M1, Ca, Mn and Na are ordered in M2, and Mg and Fe²⁺ are equipartitioned in M1 and M2.

The above considerations lead to the following geobarometric expressions for reactions (1) and (2), respectively, with P in bar and T in K

$$P = 3,944 + 13.070T + 3.5038T \ln \frac{(\alpha_{\text{Ca}}^{\text{Gt}}) \cdot (\alpha_{\text{Mg}}^{\text{Gt}})^2}{\alpha_{\text{en}}^{\text{Opx}} \cdot \alpha_{\text{an}}^{\text{Pl}}}$$
(7)

$$P = 675 + 17.179T + 3.5962T \ln \frac{(\alpha_{Ca}^{Gt})^2 \cdot (\alpha_{Mg}^{Gt})}{\alpha_{Cpx}^{Cpx} \cdot \alpha_{an}^{Pl}}$$
(8)

The calculated pressures depend on mineralogical determination of T with its inherent uncertainties, but, fortunately, expressions (7) and (8) are not sensitively dependent on T. The major source of uncertainty is the thermochemically measured standard Gibbs energies, which create pressure uncertainties of 1,400 bar for the orthopyroxene barometer and 1,700 for the clinopyroxene barometer at a given temperature. The precision of the barometers is better than this, as the ΔG° errors are nearly

Table 1 Sample data and average calculated pressures

constant. Assessment of accuracy of the barometers is more difficult. Information on this problem may be obtained by calculation of the pressures from a wide variety of granulite localities for which published mineral analyses exist.

Table 1 lists the localities, original sample numbers and descriptive data for several well documented occurrences of assemblages (1) and/or (2), representative temperatures, and calculated pressures. Immediately evident is that the clinopyroxene barometer reads 1-3 kbar lower than the orthopyroxene barometer. This discrepancy is within the combined uncertainties in ΔG° for reactions (1) and (2), and the ΔG° s could be adjusted to bring the barometers into agreement, on average. However, the pressure discrepancies may be real, and result from a greater tendency of clinopyroxene than orthopyroxene to re-equilibrate with plagioclase during uplift to lower pressures. Some information on the closure problem is given by the following pressure calculations from various terrains.

The Huntley-Portsoy and Lochnagar occurrences are hypersthene-bearing migmatites in the aureoles of the Newer Intrusions, southern Scottish Highlands²⁵. Both are sillimanitegrade, superposed on regional andalusite-bearing terrains, which suggests that the pressures should be lower than the experimental Al₂SiO₅ triple point. The Nain, Labrador granulites are in a high temperature aureole around a large anorthosite body. Pressure calculations based on the orthoferrosilite-fayalite-quartz reaction²⁶ give an average 3.2 kbar, in very good agreement with the present calculation. Buksefjorden, Greenland, Sittampundi Complex, Biligirirangan Hills and Nilgiri Hills, South India and Adirondack Highlands, New York, localities are all in large granulite tracts where sillimanite is the regional Al₂SiO₅ polymorph of intercalated metapelites. The orthopyroxene pressures agree with the Al₂SiO₅ diagram (Fig. 1) and seem more appropriate than previous pressure estimates, which would place the Adirondack⁶, Madras⁷ and Buksefjorden¹⁰ localities within the kyanite field. The Adirondack orthopyroxene pressure of $8,476 \pm 1,076$ bar based on 12 samples agrees with the current assessment²⁷ of 8±1 kbar based on revised orthoferrosilitefayalite-quartz barometry. Kyanite has been reported from the south-central Adirondacks²⁸, suggesting pressures close to the kyanite-sillimanite boundary. The Furua, Tanzania, granulite complex is a kyanite-bearing terrain²⁹, and the high calculated

orthopyroxene pressure is consistent with the experimental Al₂SiO₅ diagram (Fig. 1).

The Ronda aureole, southern Spain, and Doubtful Sound, New Zealand, granulites are tectonically uplifted portions of the deep crust^{30,31}. The Ronda granulites show a primary recrystallization at 11,100 bar followed by a secondary (corona) recrystallization at 6,480 bar. These estimates correspond closely to Obata's³² pressure estimates of two discrete recrystallizations of the Ronda peridotite mass. The Doubtful Sound mafic granulites are known, from gravity surveys, to be underlain by the upper mantle at a depth <10 km. At a distance of only 20 km inland, the New Zealand crust has a normal 40 km thickness. An average 2.8 g cm⁻³ crustal density and a 30-40 km uplift of the Doubtful Sound area implies pressures of 8.4-11.2 kbar of crystallization of the rocks now exposed at the surface.

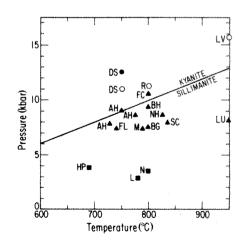

Fig. 1 Pressure calculations for various granulites. , Thermal aureoles (HP, Huntley-Portsoy; L, Lochnagar; N, Nain). , Precambrian granulite terrains (AH, Adirondack Highlands; FC, Furua Complex; FL, Finnish Lappland; M, Madras; BH, Biligirirangan Hills; NH, Nilgiri Hills; BG, Buksefjorden; SC, Sittampundi Complex; LU, Labwor, Uganda). , Deep crustal granulites (DS, Doubtful Sound; R, Ronda; LV, Lashaine Volcano). Filled symbols, orthopyroxene (reaction (1)) barometer. Open symbols, clinopyroxene (reaction (2)) barometer. Temperatures mostly from literature estimates (see Table 1).

The Lashaine Volcano, Tanzania exotic nodule suite contains clinopyroxene-plagioclase-garnet-scapolite granulites with occasional quartz, which may or may not be in textural equilibrium with the other minerals. The indicated clinopyroxene pressure of 15.5 kbar (Table 1) is an overestimate if quartz is not actually part of the primary equilibrium assemblage, but is in agreement with Irving's 33 experimental conclusion that very similar nodules from Delegate, Australia, equilibrated with their source at 14-17 kbar. Such scapolite granulites may be prominent components of the lower crust³⁴.

Everything that is known about the crystallization pressures of the occurrences tabulated here seems to agree with the orthopyroxene (reaction (1)) geobarometer. The strongest indications of its validity are comparison with the experimental Al₂SiO₅ diagram and the orthoferrosilite-fayalite-quartz geobarometer. This evidence suggests that reequilibration to lower pressures after the peak of metamorphism has had minimal effect on the pressure indication of reaction (1). The two barometers can be made to agree on the average within the uncertainties of the thermochemical measurements by a balanced readjustment of the ΔH° s and ΔS° s leading to the following expressions:

$$P(\text{opx}) = 3,694 + 12.820T + 3.5038T \ln K_1$$

$$P(\text{cpx}) = 1,425 + 17.929T + 3.5962T \ln K_2$$
(9)

These readjustments give the maximum allowable increase in the clinopyroxene pressure with only a small decrease in the orthopyroxene pressure. A test of the modified clinopyroxene barometer and some information on the delayed closure problem may be possible using lower-crustal two-pyroxene garnet granulite samples from explosive pipes³⁵, which are effectively quenched from deep-seated conditions. We have not yet found sufficient published data of this kind for a definitive test.

A firm result of this study is that the continental crust was, locally, at least, of thickness approaching or exceeding that of the present normal thickness as long ago as the late Archaean. A proposed high-temperature, low-pressure charnockite geotherm³⁶ is not supported. The remarkable cluster of Precambrian granulite pressures (Fig. 1) at $8.5 \pm 2 \text{ kbar}$ (opx barometer) for nine different terrains suggests that a certain repeated mechanism of high grade metamorphism has been operative. For the western Grenville this mechanism may have been continental collision, as the abortive rift of the North American continent which began ~1.400 Myr ago, closed ~1,100 Myr ago, generating the Grenville orogeny. The Grenville supracrustals were buried at 30 km depth in a doubled continent³⁷. Continental collision with temporary doubling of the crust has been proposed to explain the apparently high pressures of late Archaean metamorphism also³⁸. Great uplift in post-Precambrian times exposing deep crust and even upper mantle would seem to be required by the high pressures of the Doubtful Sound and Ronda occurrences.

We thank J. N. Berg, S. R. Bohlen, E. C. Hansen and A. S. Janardhan for unpublished mineral analyses, and W. L. Griffin for helpful comments. This research was supported by NSF grant EAR 78-15939 (R.C.N.). Some of the Indian granulites described here were gathered and analysed under an NSF grant, EAR 79-05723 (R.C.N.).

Preservation of polyunsaturated fatty acid in ancient Anasazi maize seed

David A. Priestley*, Walton C. Galinat† & A. Carl Leopold*‡

* Boyce Thompson Institute, Ithaca, New York 14853, USA † University of Massachusetts, Suburban Experiment Station, Waltham, Massachusetts 02154, USA

Oxidation of polyunsaturated fatty acids (PUFAs) is widespread in animal tissues and has been implicated in senescence¹ and as a cause of deterioration of stored seeds². Although signs of lipid oxidation have been detected in seeds during long-term storage3, little is known of the magnitude of the change induced in the PUFA fraction. In conditions of 'accelerated ageing' (saturating humidity and 45 °C) in soybean seeds, the PUFA content has been reported to decline within a few days4, but in somewhat milder conditions PUFAs are not oxidized during the time when germinability is lost⁵. An extreme case in which to estimate the extent to which PUFAs may be oxidized comes from the examination of ancient maize seeds from caves in the southwestern United States, where the arid climate is conducive to the preservation of biological materials⁶. We have now compared new seeds with seeds which were 1-17 centuries old, and report that most of the linoleic acid (by far the predominant PUFA in this species) is oxidized in the first 100-200 yr, but some is still detectable in seeds more than 1,500 yr old. We believe this represents the oldest sample of PUFA so far reported.

Modern maize seeds (Zea mays L.) contain ~5% lipid, most of which is neutral storage lipid. Four principal fatty acids are found (C18:2>C18:1>C16:0>C18:0). In a representative modern North American variety about half of the fatty acid is linoleic, C18:2 (Table 1; cv. Early Cornell Synthetic). The polar lipids of these seeds display a fatty acid profile rather similar to that of the storage lipid fraction. Increasing evidence indicates that maize has evolved through several thousand years of artificial selection from the annual teosinte (Z. mexicana (Schräder) Kuntze)^{7,8}. In agreement with an earlier study⁹, we

The lipids of ground seed particles (0.8-1.6 g) were extracted with chloroform-methanol (2:1, v/v) and the fatty acids prepared for gas chromatography as previously described. Separations were performed either on a 1.8×4 mm internal diameter glass column packed with 3% Silar-5CP on 100/120-mesh Gas Chrom Q or a 1.8×2 mm glass column packed with 10% DEGS-PS on 80/100-mesh Supelcoport. Additional details are given in ref. 5. Values given are the mean (and range) of two injections. Traces of linolenic acid (C18:3) in recent samples have been ignored.

Table 2 Provenance of old maize seeds

Sample no.	Race or variety	Date AD (and cultural affiliation)	Location	Ref.
1	Evolved Chapalote	100-500 (Basketmaker)	Cave II, March Pass, Kayenta, Arizona (PM: A 2481)	12
2	Early Chapalote	100-500 (Basketmaker)	As above (PM: A 2481)	12
3	Near Chapalote	200-700 (Basketmaker)	Site SR 16-6, Dirty Devil-Waterhole Flat, Utah (PM: 10/264)	24
4	Near Maíz de Ocho	700-1300 (Kayenta Anasazi)	Cave 8, Sagiotsosi Canyon, Kayenta, Arizona (PM: A 3520)	. 12
5	Dented Chapalote	950-1200 (Fremont)	Site PR4-31, Nine Mile Canyon, Utah (PM: A 7769)	24
6	Florida White Dent	1883	Central Kentucky (WCG)	
7	Leaming Dent	1902	Agricultural Expt. Station, Urbana, Illinois (WCG)	

The age ranges given for the ancient seeds are derived from the stratigraphy of the sites and are consistent with the overall pattern of maize evolution. Further details are given in ref. 12. PM, Catalogue number of the Peabody Museum, Harvard University; WCG, private collection of Dr Walton C. Galinat.

found that contemporary seeds of annual teosinte contain less lipid than maize. The proportions of the fatty acids are similar for maize, annual teosinte and a recently discovered perennial teosinte (Z. diploperennis Iltis, Doebley and Guzmán)¹⁰ (Table 1). In each of these contemporary seeds, linoleic acid constitutes >40% of the total fatty acids present¹¹. It is likely that the original content of linoleic acid in the ancient maize seed would have matched or exceeded this value.

Maize has been associated with the Anasazi culture of the American South-West from the first appearance of its earliest representatives (the Basketmaker people) around AD 100. This association continued throughout the Classic Pueblo period and into the recent era of European influence. The changing morphology of the maize races during this long period has been studied in some detail¹². We examined four samples of maize from various periods of the Anasazi culture (Tables 1 and 2, samples 1-4) and one sample from the closely related Fremont

culture (sample 5). We also investigated maize seed grown during the past 100 yr (samples 6 and 7). The provenance of the seeds is detailed in Table 2. The ages assigned to the seeds are consistent with the stratigraphy of the sites from which they were obtained and with the overall pattern of maize evolution 12. All these seeds were non-viable. When received for analysis their water content was ≤5-6%. All the ancient seeds showed excellent external preservation, and gave a light or dark brown meal when ground. The single Fremont sample (no. 5) was unusual in having adhering soil particles (presumably indicative of a moist environment) and in being extremely friable, readily crumbling into a fine dust when ground.

With the exception of the Fremont seed, all the samples contained linoleic acid (Table 1). The relative proportion of the three other fatty acids followed the customary maize-teosinte pattern (C18:1>C16:0>C18:0). Similar results were obtained whether we used a cyanosilicone phase or a polyester

phase for the gas chromatographic analysis. The presence of the C18:2 in the oldest seeds has been further confirmed by combined gas chromatography-mass spectrometry (data not shown). Results were comparable with those of Table 1 when the fatty acids of the polar (presumably primarily membrane) lipid subfraction were examined (data not shown). The PUFAs of the storage lipid fraction and the membrane lipid fraction were therefore about equally susceptible to oxidation. The data of Table 1 suggest a relatively rapid decline in linoleic acid during the first 100-200 yr of storage, leaving a small proportion of linoleic acid which is comparatively stable for much longer.

The proportion of palmitic acid (C16:0) in the Fremont sample exceeded that of oleic acid (C18:1). In these badly preserved seeds, even the monoenoic fatty acid was probably subject to enhanced degradation compared with the fully saturated acids. The well known deleterious effects of damp soil on ancient seeds13 probably led to loss of oleic acid in the Fremont seeds. On the other hand, prolonged dry storage of the well preserved Anasazi seeds (samples 1-4) was sufficient to remove only ~80% of the linoleic acid and scarcely any of the oleic.

Although preservation of monoenoic fatty acids has been noted in well stored Roman oil samples from the second century AD^{14,15} and brain lipids of a 40,000-yr-old frozen mammoth¹⁶, a badly deteriorated Egyptian oil sample originating from the sixth century BC lacked all but the fully saturated fatty acids¹⁷. PUFAs were absent in each case.

It is unlikely that the linoleic acid in the Anasazi seeds represents contamination, microbial or otherwise, because both the total (primarily neutral) lipid fraction and the quantitatively minor polar (membrane) lipid subfraction yielded similar results and it is most unlikely that these two different fractions would be contaminated to approximately the same extent in every sample.

The long-term preservation of linoleic acid is consistent with reports that some membrane structure can be preserved in ancient seeds, which suggests the presence of sufficient membrane lipid to permit a bilayer structure. Both membrane profiles in Egyptian wheat seeds from the third and fifth millenia BC18 and ample membrane preservation in 'fossil' Indian lotus seeds¹⁹ (exact age uncertain)²⁰ have been reported. The widespread occurrence of tocopherols in seeds²¹ doubtless serves to minimize the prevalence of PUFA oxidation during storage.

Our data refer to changes which occur in maize seeds post mortem, and do not relate directly to the debate about the relevance of lipid peroxidation to loss of seed viability^{4,5,22,23} However, they do indicate that the extensive PUFA oxidation which may occur in seeds during a few days or weeks of 'accelerated ageing' in the laboratory may take many decades or centuries in drier and cooler conditions. Furthermore, the retention of significant amounts of linoleic acid after 1.500 yr or more of storage emphasizes the unusual capacity of dry seeds to protect at least part of their susceptible components from atmospheric oxidation.

We thank Dr H. Everett and Bill Tracy of Cornell University for recent seed of maize and perennial teosinte, and Dr Alan Renwick for gas chromatography-mass spectrometry analysis.

Lack of correlation between extracellular polysaccharide and nodulation ability in Rhizobium

Richard Sanders*†, Elisabeth Raleigh† & Ethan Signer†

- * Department of Chemistry, University of Colorado, Boulder, Colorado 80309, USA
- † Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Rhizobia are Gram-negative bacteria normally capable of nodulating the roots of leguminous plants, and the failure of five EPS (extracellular polysaccharide)-deficient mutants to nodulate suggested that EPS is required for this nodulation. However, we report here that among a larger sample of mutants with altered EPS production, isolated from two species of Rhizobium (including one of the original set plus 34 new ones), production of EPS is not correlated with ability to nodulate appropriate hosts. Therefore, although involvement of a minor EPS component cannot be ruled out, there is no evidence that gross EPS is required for nodulation.

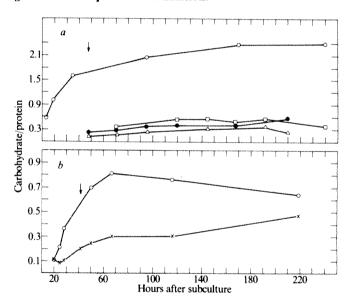

Fig. 1 a, Bacteria were grown in MBM⁴; 1 ml of a fresh stationary-phase culture was inoculated into 100 ml of fresh medium and shaken at 30 °C, and a 10-ml sample was taken at each time point. Arrows indicate the onset of stationary phase. Aliquots (5 ml) of each sample were passed through a 0.45-µm Millipore filter and the filtrate dialysed against three changes of distilled water before being assayed for carbohydrate using the anthrone method3. The remaining 5 ml were dialysed as above and assayed for protein by the Lowry method8. Numbers are glucose-anthrone units per bovine serum albumin Lowry unit. Each point represents the average of a least three independent experiments. We have examined the residual anthrone-positive material made by R. leguminosarum 128c53 str' rif' RS1 and found that ~50% of it is excluded from Sepharose 4B, where essentially all wild-type material enters the column. This peak of aggregated or highmolecular-weight material is rich in 2-keto-3-deoxyoctanoic acid9, suggesting that it consists of cell wall fragments rather than extracellular material 10. Therefore, low EPS values are likely to be overestimates, and we do not consider that the assay used here is accurate below 10% of wild-type production. O, 128c53 str' rif';

a, Strains were assayed for EPS at 96 h after a 1:100 dilution of a stationary-phase culture into fresh medium as described in Fig. 1 legend. All values represent the average of at least three independent experiments. For nodulation assays pea seeds were surface sterilized by stirring in 30% H₂O₂ for 60 min, planted in a sterile 1:1 mixture of perlite and vermiculite (Grace), and watered daily with sterile distilled water. R. leguminosarum 128c53 str' rif' and its derivatives (5 ml) were grown with shaking at 30 °C to stationary phase in modified Bergersen's medium (MBM)⁴, resuspended in 5 ml of sterile water and inoculated onto 18-day-old Early Market (Agway) pea seedlings. The seedlings were grown at 26 °C with a 14-h light/10-h dark cycle, illumination by 3,000 ft-candles, and collected at day 21. All values represent the average of at least three independent experiments, each of which contained at least three plants. In each experiment at least three seedlings were inoculated with R. leguminosarum 128c53 str rif as positive control. Negative controls for each experiment were several uninoculated plants equal to the number of experimentally inoculated seedlings. Experiments in which the negative controls contained any nodules were discarded. Nodules were surface sterilized by stirring in 70% ethanol for 5 min, crushed, resuspended in sterile water, and spread on plates containing MBM for inspection of colony morphology. From RS2, 3 and 4 we recovered only non-slime-forming colonies identical to the inoculum. From rare nodules formed on plants inoculated with RS1 and RS5-16 we occasionally recovered colonies, usually a mixture of wild (slime-forming) and mutant types but sometimes mutant only; the slime-formers nodulated with wild-type efficiency and are presumed to be revertants. We found rare nodules with RS1, in contrast to the initial study, possibly due to differences in cultivar or conditions of temperature and light. b, Strains which prefixed ER were isolated from 127K26; FB308 was isolated from FB30, a streptomycin-resistant derivative of 127K26 (E.R., in preparation). For convenience, mutants are grouped by classes, to be described elsewhere. Cultures were inoculated 1:500 into fresh medium and collected 48 h after stationary phase was attained. Values are the average of three independent experiments for all except FB30, ER1 and ER8, which are the average of two independent experiments. ER1, which cannot use glutamate, was grown in MBM+0.2%(NH₄)₂SO₄; the value is in comparison with 127K26 grown in the same medium (which gave a value of 98% of that for MBM alone). For the nodulation assays, five independent colonies of each mutant strain, six of FB30 and seven of 127K26 were grown in YAP (0.1% yeast extract, 0.1% L-arabinose, 0.5×10⁻⁴ M Na₂HPO₄, 6.65 × 10⁻³ M KH₂PO₄, pH 6.6)⁵ with 5 mM MgSO₄ added, for 3 days. Plants were inoculated with ~5 × 10⁸ bacteria for each culture. Each culture was tested at the time of inoculation by cross-streaking against five typing phages. Plants were prepared for the nodulation assay according to Beringer⁶ except that Fahraeus medium⁷ containing 1% agar was used. Seedlings were grown as described in a. Nodulation was monitored every 2-3 days by inspection for 15-20 days, at which time the plants were collected. Nodules began to appear on day 6; all strains recorded as >60% for nodulation had produced red nodules by day 12, and gave positive acetylene reduction assays for excised nodules at the time of collection. Plants inoculated with wild-type 127K26 had 50-150 nodules (average ~100) in various stages of development at the time of collection. Nodules were counted individually, up to 70, and the number remaining was estimated by eye. No nodules were found for any strain listed as <0.2, ER204 yielded one white nodule, among the five plants inoculated, which contained bacteria like the inoculum; two plants inoculated with ER6 yielded a total of 28 nodules which contained only revertant bacteria, as judged by colony morphology and phage type. A plant inoculated with YAP only had no nodules

RS1 of Rhizobium leguminosarum 128c53 str' rif' is EXO-1 of ref. 1; the remaining mutants of this strain were isolated by the membrane-filter technique previously described1. EPSdeficient derivatives of Rhizobium phaseoli 127K26 were found among survivors of exposure to bacteriophage F1, isolated from soil².

Figure 1 shows the kinetics of EPS production after subculture (see Fig. 1 legend) for R. leguminosarum 128c53 str' rif', R. phaseoli 127K26 and several of their EPS-deficient mutants. Table 1 compares EPS production, as measured by the anthrone method3, at 96 h after subculture (compare with Fig. 1), with nodulation ability for all mutants.

The main finding is that one mutant of R. leguminosarum, RS4, and five mutants of R. phaseoli, ER3, 13, 17, 24 and 26, make <10% of wild-type anthrone-positive material, yet nodulate normally. Other mutants have intermediate EPS and normal nodulation (ER2, 19), intermediate EPS and intermediate nodulation (RS3), intermediate EPS and little or no nodulation (RS8, 9, 13, 15, 16; ER1, 15, 16, 21, 23, 204), little EPS and poor nodulation (RS2), and even excess EPS and no nodulation (ER20).

Obviously, the crude methods used here do not distinguish between different carbohydrate components of EPS and our data would not reveal whether a minor component of EPS was

essential for nodulation. Nevertheless, it is clear that gross EPS production cannot be used as an indicator of nodulation ability and, therefore, that there is no evidence of a requirement for EPS in nodulation.

Do carbonate skeletons limit the rate of body growth?

A. Richard Palmer

Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9
Bamfield Marine Station, Bamfield, British Columbia, Canada V0R 1B0

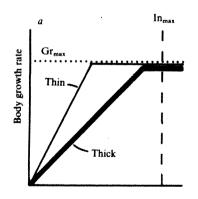

Many marine invertebrates produce mineralized skeletons whose form suggests an economical construction. Porous as opposed to solid skeletal components are produced by scleractinian corals1.2, balanoid and coronuloid barnacles3, ostreid and hippuritid bivalves4, and almost all modern echinoderm classes^{5,6}. They were also produced by rudist bivalves which were widely successful in Cretaceous tropical seas7. Marine prosobranch gastropods produce a stout external shell sculpture in place of a uniformly thick, ultimately stronger shell^{8,9}. The costs implied by these patterns of economical skeleton construction, however, are unknown¹⁰⁻¹². The term 'cost' refers to an evolutionary cost measured in terms of reduced fitness. Note that not all such costs are energetic; non-energetic constraints may also influence fitness. I present here evidence that both thick- and thin-shelled morphs of Thais (=Nucella) lamellosa (Gastropoda, Prosobranchia) produce shell material at a remarkably similar rate during maximal growth. Thick-shelled animals, however, exhibit a significantly slower rate of body growth. These results suggest that rates of skeletal growth can limit the rate of body growth and that this limitation represents a potentially important evolutionary cost.

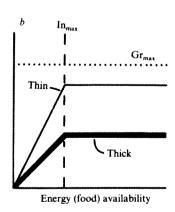

Costs associated with carbonate skeletons can be subdivided into at least three categories: (1) an energetic, depositional cost including organic matrix production and mineralization; (2) an energetic, post-depositional cost, limited primarily to organisms that must expend energy transporting a skeleton; and (3) a non-energetic, growth-rate-limitation cost where the rate of maximal body growth may be set not by the energy available for growth but rather by the maximum rate at which skeleton may be produced. This latter cost is important to recognize because different patterns of energy consumption and growth will be exhibited with increasing availability of energy than would be expected if skeleton costs were strictly energetic.

Figure 1 illustrates the relationship between body growth and increasing energy (food) availability for three alternative hypotheses about factors which potentially limit body growth rate. Predictions about the relative rates of shell growth and rates of energy consumption for each hypothesis are included in Fig. 1 legend. The first hypothesis (Fig. 1a) predicts that if a physiologically determined upper limit to the rate of tissue production (dotted line) is reached before some upper limit to the rate of ingestion or assimilation (dashed line), rates of body growth in organisms with thick and thin skeletons will be identical when energy availability is high. Given an energetic cost to shell material, however, organisms with a thick or dense skeleton will require more energy to achieve the same rate of body growth because of additional energy expended in producing more skeletal material. The second hypothesis (Fig. 1b) predicts that if an ingestion (or assimilation) limit (dashed line) is reached before a tissue production limit (dotted line), then organisms with thick or dense skeletons will exhibit a lower maximal rate of body growth than those with thin or porous skeletons. Here, organisms with thick and thin skeletons should ingest (assimilate) equal amounts of energy at high energy availability, but because of energy invested in shell, thick-shelled animals should have a slower rate of body growth.

The third hypothesis (Fig. 1c) predicts that if a shell production limit is reached before either an ingestion or a tissue production limit, organisms with thick skeletons will again show slower rates of body growth at high energy availability, as with hypothesis b. However, because body growth cannot proceed in advance of skeleton growth, organisms with thick or dense skeletons should consume less energy (food) than those with thin or porous skeletons.

To test these hypotheses, pre-reproductive individuals of similar body weight (Table 1) were selected from a thick- and a thin-shelled population of the morphologically variable, intertidal gastropod, Thais lamellosa. Although having similar body weights, thick-shelled individuals had almost 50% heavier shells (Table 1). Growth experiments (Tables 1, 2) demonstrated that both thick- and thin-shelled animals added significantly less shell (mean, 22.6% less) and less tissue (mean, 25.2% less) at the upper than the lower tidal level. At both tidal levels, however, thick-shelled animals consumed fewer barnacles (Table 3) and also gained less body weight (mean, 32.5% less). Of particular interest is the fact that thick- and thin-shelled animals of the same initial body size produced almost equal weights of shell material at both tidal heights. These patterns of growth and prey consumption are inconsistent with the first two hypotheses (Fig. (1a, b), and support the skeleton-limitation hypothesis (Fig. (1c))

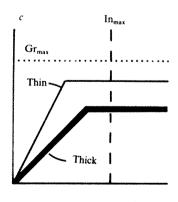

Fig. 1 Graphical illustration of hypothetical growth patterns with increasing rate of energy (food) supply for thick- and thin-shelled organisms subject to different growth constraints. a, Maximum rate of body growth limited by maximum rate of tissue production. b, Maximum rate of body growth determined by maximum rate of ingestion (or assimilation). c, Maximum rate of body growth determined by maximum rate of shell production. Predicted differences in rates of shell production at maximum body growth rate are: a, b, thick > thin; c, thick = thin. Expected energy (food) intakes at maximum body growth rate are: a, thick > thin; b, thick = thin; c, thick < thin. These differences will only be true when animals are growing at a maximum rate. In_{max} , potential maximum rate of ingestion (assimilation). Gr_{max} , potential maximum rate of body growth. Thin-lined curve, organism with low-density skeleton or thin shell; thick-lined curve, organism with high-density skeleton or thick shell.

Note for hypothesis c that the inflection points of the two curves need not coincide on either axis, in contrast to hypotheses a and b.

Table 1 Size and growth parameters for thick- and thin-shelled T. lamellosa

				Initial		Total we	ight change
Tidal height (ft)	Morph	n	Shell length (mm)	Shell weight (g)	Body weight (g)	Shell weight (g)	Body weight (g)
0.0	Thick Thin Thick Thin	10 9 14 15	21.9 (1.08) 22.2 (1.26) 21.6 (0.95) 21.5 (1.67)	1.68 (0.370) 1.06 (0.169) 1.59 (0.208) 0.95 (0.216)	0.23 (0.052) 0.24 (0.042) 0.22 (0.039) 0.23 (0.045)	1.43 (0.309) 1.49 (0.177) 1.06 (0.260) 1.19 (0.329)	0.37 (0.133) 0.50 (0.092) 0.25 (0.074) 0.41 (0.138)

Values are means and standard deviations of size and growth parameters for thick- and thin-shelled *T. lamellosa* pooled from replicates at two tidal heights. Thick-shelled animals were collected from False Bay and thin-shelled animals from Turn Rock, both located on San Juan Island, Washington, USA. Shell and body weights were measured non-destructively by methods described elsewhere Replicate groups of individually marked, measured and weighed animals of each shell type were placed in plastic screen cages mounted on pilings at two tidal heights (0.0 and +2.0 ft above MLLW⁴¹) at the Friday Harbor Laboratories, Friday Harbor, Washington, USA. Throughout the experiment the *Thais* were supplied freely with their preferred prey, *Balanus glandula*, on small stones 1. Prey were made available at all times in high densities so that searching times were negligible. Snails were supplied with barnacles from 13 August to 5 September and 14 September to 14 October, and final body weights (wet) were measured on 13 November, 1978. n, Total number of individuals in each treatment. Numbers in parentheses are pooled standard deviations. There were two replicate cages for each treatment at the lower, and three for each treatment at the upper tidal level.

Table 2 Analysis of variance on initial values and two growth parameters of thick- and thin-shelled T. lamellosa at two tidal heights

Consumption rates were measured as barnacles eaten per snail per day from 14 September to 14 October, 1978. Each value represents an average for five snails (individual consumption rates are not known as five snails were contained in each cage). An analysis of variance was performed on these average values: d.f., degrees of freedom; MS, mean square; P, exact probability.

* Significant F ratios.

that rate of shell production limits the maximum rate of body growth. However, these data cannot rule out the possibility that animals from the thick-shelled population consumed barnacles more slowly for other reasons and that the production of equal weights of shell material was coincidental. That this occurred at both tidal heights due to chance alone seems unlikely.

Two otherwise enigmatic patterns of invertebrate growth may be explained by the skeleton-limitation hypothesis. First, shell production continues in the absence of feeding in species of barnacles¹³, meso-¹⁴ and neogastropods (A.R.P., unpublished results), and both pteriomorphian^{15,16} and heterodont¹⁷ bivalves. Although difficult to explain energetically, this may reflect either an increase in a shell's habitable volume in anticipation of future body growth or a reinforcement of thinner shell produced during periods of more rapid growth¹⁸. Second,

scleractinian corals frequently show seasonal changes in the density of skeletal material produced. Higher density bands are generally believed to form during periods of slower growth (refs 19-22). In both examples, energetic considerations would predict a decrease in skeleton production when tissue growth decreases or stops, yet calcification continues. Both examples would thus seem to be more readily explained as a response to skeleton-limited rates of body growth, rather than as a result of a high energetic cost to skeletal material.

A third growth pattern may also be explained by the skeleton-limitation hypothesis: rapidly growing organisms frequently produce less skeleton per unit body weight (for example, species of ramose scleractinian corals^{20,23}, pteriomorphian²⁴ and heterodont²⁵ bivalves, echinoids²⁶ and echinoderms in general²⁷). In addition, a number of organisms exhibit ontogenetic

changes in skeletal growth. Juveniles, for whom maximal growth may be critical^{9,28}, exhibit more porous or, in some cases, significantly less massive skeletons than adults (for example, species of balanoid and coronuloid barnacles^{29,30}, strombid and cypraeid gastropods^{31,32} and some extinct armoured heterostracan fishes³³). Although juveniles are more vulnerable than adults to most predators, a heavier skeleton could limit the rate of body growth, increasing the time spent at smaller, more vulnerable sizes⁸. When mature and slow growing, skeletal reinforcement would no longer restrict potential growth. Where there is a refuge in size from predation, trade-offs between rate of growth and extent of morphological defence may represent an important compromise.

Step(s) which limit the rate of skeleton production are unknown. Neither rates of ion transfer across epithelia³⁴ nor availability of dissolved calcium carbonate in surface seawater (<100 m; refs 35-37) are likely to limit the rate of skeletal growth. A probable limiting step is the rate at which crystals can grow from a biologically maintainable precipitating medium. If this is the case, during rapid growth crystal growth limitations would favour shell microstructures with many small crystals because of the increased surface for precipitation. Limited data reveal such a pattern in comparisons of seasonally rapid and slow growth increments in two bivalve species³⁸. Furthermore, both bivalved^{4,39} and shelled gastropod³⁹ molluscs exhibit an evolutionary loss of nacre, a shell microstructure composed of large crystal elements. Thus both ecological and evolutionary patterns in skeletal architecture may be explained by the skeleton-limitation hypothesis.

The above evidence indicates that a potentially important non-energetic 'cost' exists due to growth constraints imposed by carbonate skeletons, both for marine gastropods and possibly for other marine invertebrates. The prevailing attempt to explain morphological adaptations purely in terms of energetic costs and benefits may be too narrow a perspective.

Segment-specific organization of leg motoneurones is transformed in bithorax mutants of Drosophila

Steven H. Green

Division of Biology 216-76, California Institute of Technology, Pasadena, California 91125, USA

In Drosophila, genes controlling segmentation in the thorax and abdomen are clustered in one region of the genome known as the bithorax complex. Studies of the genetics of this complex suggest that loss of activity of a gene causes transformation of a particular segment to a more anterior one, mesothorax representing the ultimate transformation¹. This transformation is well described for the epidermis, but it is not clear whether other segmentally arranged tissues are also transformed. The segmental ganglia are fused in Drosophila into a single compact mass termed the thoracic ganglion but the segmental organization of the nervous system is still apparent. There are discrete regions of neuropil, termed neuromeres, corresponding to the three thoracic segments: prothorax, mesothorax and metathorax. A small terminal neuromere corresponds to the abdominal segments. Evidence is presented here that the leg motoneurones of each of the three thoracic segments are arranged in a segment-specific pattern in the thoracic ganglion. In mutant flies which have the metathoracic cuticle transformed to mesothoracic, the arrangement of the metathoracic leg motoneurones can be altered to resemble that of the mesothoracic leg motoneurones.

Horseradish peroxidase (HRP) filling of cells was used to study the innervation of the leg. This enzyme is applied to a cut made in the tarsus and is transported through those sensory axons that have been cut. It is also taken up by motoneurone terminals and transported in a retrograde fashion to fill the entire cell. The HRP-filled cells can be visualized by any one of several methods^{2,3}. Figure 1 is a composite drawing showing leg motoneurones in each neuromere. The arrangement of the leg motoneurones is different in the three neuromeres: in the prothoracic (anterior) neuromere, the cell bodies are in a region of the cortex anterior to the neuropil. The axons project back into the neuropil, into which they branch, collect into a loose bundle and course laterally and ventrally to leave the ganglion in the prothoracic leg nerve. In the mesothoracic (middle) neuromere, the cell bodies are in the cortex anterior and ventral to the neuropil. The axons project posteriorly to exit through the mesothoracic leg nerve. Branches are directed dorsally into the lateral neuropil, segregated from sensory neurone arborizations which are in the medial region. In the metathoracic (posterior) neuromere, the motoneurone cell bodies lie laterally and somewhat posteriorly to the neuropil. Their axons project anteriorly from the cell bodies, then loop back and run posteriorly to the nerve. All the axons loop back at the same point although the cell bodies are spread through a region 30-60 µm posterior to the loop. As in the mesothoracic neuromere, the arborizations of the motoneurones are laterally placed in the neuromere, not overlapping the medially placed arborizations of the sensory neurones. In each neuromere a single motoneuron sends a branch contralaterally. These cross in commissures located posteriorly in the prothoracic and mesothoracic neuromeres but anteriorly in the metathoracic neuromere. In the mesothoracic neuromere this motoneurone has its cell body located anteriorly to the other motoneurone cell bodies. Thus, in terms of the positions of the leg motoneurone cell bodies and of the commissure, the metathoracic neuromere is the reverse of the anterior two neuromeres along the anteriorposterior axis.

Similar results were obtained by cobalt filling of axons at the cut end of the coxa, using a method described elsewhere⁴. Furthermore, observations of silver-stained ganglia by Power⁵ and repeated in this laboratory reveal large cells with an arrangement and nuclear morphology like that of the backfilled motoneurones. Therefore, the differences in the motoneurone pattern in the three neuromeres do not seem to result from uptake of HRP by different subpopulations of an identically arranged motoneurone population in each neuromere. The arrangement of the leg motoneurones as described above is the same in males and females of the *Drosophila melanogaster* wild-type strains Canton-S and Oregon-R, the mutant spineless-aristapedia and *Drosophila virilis*.

The bithorax complex mutations abx (ref. 6) and bx transform anterior metathorax to anterior mesothorax; pbx does the same to the posterior compartment. Flies of the genotypes abx bx^3 pbx/abx bx^3 pbx and abx bx^3 pbx/Df(3R)P2 (ref. 7) (derived from stocks provided by Dr E. Lewis) can have the cuticle of the metathoracic segment almost identical to that of the mesothoracic, although expression (degree of change) is variable and incomplete transformations are seen. In all cases studied, the

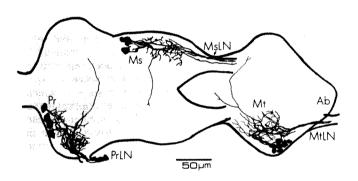

Fig. 1 A wild-type thoracic ganglion is shown in horizontal plane. This drawing is a composite of three separate backfills, traced from photomicrographs on to one thoracic ganglion outline. Only one side is shown for each neuromere. As many as nine motoneurones have been filled from a given leg but generally fewer are seen as in the pro- and mesothoracic examples shown here. In anterior to posterior order, the prothoracic (Pr), mesothoracic (Ms), metathoracic (Mt) and abdominal (Ab) neuromeres are labelled. Leg nerves: PrLN, prothoracic; MsLN, mesothoracic; MtLN, metathoracic. Sensory axons filled in these preparations were not included in the drawings. The motoneurones were filled by applying 20% HRP+3% α -lysolecithin to a cut at the distal end of a leg. Backfill time was 10-14 h. The ventral thorax as removed and fixed with 1.25% glutaraldehyde + 1% formaldehyde in 0.1M phosphate buffer (pH 7.3) for 30 min. The ganglion was removed from the cuticle, fixed for an additional 45 min and washed three times for 30 min in phosphate buffer + 10% sucrose. The HRP was visualized by one of the following two methods: (1) The ganglion was washed two times for 5 min in Yates reagent (1.5 mg ml⁻¹ in 0.05M Tris buffer, pH 7.6), and then incubated for 3-6 min in fresh reagent + 0.006% hydrogen peroxide. The reaction, which colours the HRP-filled neurones reddish-brown, was observed with a dissecting microscope to determine the appropriate end point. The ganglion was then washed three times for 5 min in Tris buffer, dehydrated in ethanol (1 min each 70% and 95%, three times for 1 min in 100%), cleared in methyl salicylate and mounted in immersion oil. (Method modified from ref. 2.) (2) The ganglion was kept for 15 min in a medium made up as follows: 0.25 ml of 3,3', 5,5'-tetramethylbenzidine solution (2 mg ml⁻¹ in 100% ethanol) was added to 10 ml of sodium ferricyanide solution (1 mg ml⁻¹ in 0.01M acetate buffer, pH 3.3), both solutions freshly made up. Hydrogen peroxide was then added to a final concentration of and the ganglion kept in this for 4-6 min. This reaction colours the HRP-filled neurones blue. As above, the actual reaction time was determined by observing the reaction with a dissecting microscope. The ganglion was washed three times for 5 min with acetate buffer and further processing was as described above. (Method modified from ref. 3.)

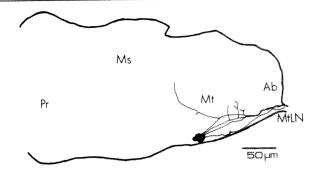

Fig. 2 A thoracic ganglion from an animal of genotype $abx bx^3 pbx/abx bx^3 pbx$ is shown in horizontal plane. A metathoracic leg was backfilled and the HRP visualized as for method (1) in Fig. 1 legend. Labelling as in Fig. 1.

metathoracic leg itself was completely transformed into a mesothoracic leg, as determined by the pattern of leg bristles. Metathoracic legs of these flies were cut and HRP applied as for the wild-type flies. Of 27 successful backfills, four showed altered patterns of motoneurone arrangement that resembled mesothoracic motoneurones and nine showed intermediate phenotypes; unusually positioned motoneurones, suggestive of a mesothoracic pattern but resembling neither pattern entirely. The remaining 14 backfilled legs showed the wild-type arrangement of motoneurones. Of 41 successful metathoracic leg backfills in flies wild-type for bitherax, no deviations from the metathoracic pattern were ever observed. This is consistent with the hypothesis that the central nervous system (CNS) can be segmentally transformed by the mutations. As with the epidermis, expression is variable although the expression and penetrance (fraction of flies affected) of the mutations are far less in the CNS than in the cuticle.

Figure 2 exemplifies a metathoracic neuromere with a mesothoracic pattern of motoneurone arrangement. The motoneurone cell bodies lie anteriorly and ventrally in the cortex and the axons project posteriorly through the neuropil. Figure 2 also shows that the cell which projects contralaterally is anterior to the other cells, just as in the mesothoracic neuromere. Thus, a unique metathoracic neurone seems to be converted into its mesothoracic homologue. Nevertheless, the transformation to the mesothoracic is not complete. The contralaterally projecting fibre takes an anterior route as in the wild-type metathoracic neuromere.

Two examples of intermediate phenotypes are shown in Fig. 3: a shows a metathoracic neuromere containing motoneurones in intermediate positions; b shows a ganglion with metathoracic leg motoneurones that are positioned properly but have axons that project posteriorly into the nerve instead of looping anteriorly. Possibly, cell body position and direction of axon growth are under separate control by anterior-posterior information.

Previous neuroanatomical studies^{8,9} of bithorax using these mutants to study sensory projections from the ectopic cuticle raised the question of whether the mutations affect the CNS itself. Palka et al.⁸ found sufficient differences between bithorax and wild-type ganglia and sensory pathways to suggest that the CNS was altered by the mutations. They found additional evidence for this by considering the pattern of projection of sensory neurones from clones of mutant cuticle into presumably wild-type ganglia. Ghysen⁹, stressing the overall anatomical similarity of wild-type and bithorax ganglia and sensory pathways concluded that the CNS was not altered in the specific pathways studied.

I have approached the question directly by studying neurones with cell bodies in the CNS, using the recently constructed combination abx bx^3 pbx to obtain more extreme transformations than were previously available. The observations reported here do not imply that the genes of the bithorax complex directly control the CNS segmental pattern. They may

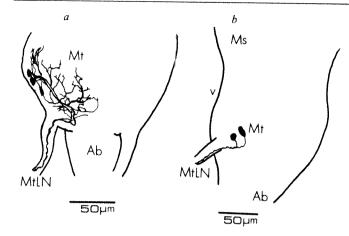

Fig. 3 Two 'intermediate' transformations. a, A thoracic ganglion from an animal of genotype abx bx3 pbx/abx bx3 pbx in horizontal plane. A metathoracic leg was backfilled and the HRP visualized using method (1) of Fig. 1 legend. b, A thoracic ganglion from an animal of the genotype $abx bx^3 pbx/$ Df(3)P2 in sagittal plane, V marking the ventral surface. result from a direct effect of the genes in another tissue, which in turn affects the CNS by induction or by mechanical constraints on CNS growth. Experiments using mosaic flies should determine which tissue must be mutant for the pattern of organization of leg motoneurones to be transformed. This should help to elucidate the mechanisms underlying segmental differences in the CNS.

I thank Dr Ronald Konopka for advice throughout this work and A. Ferrus, E. Lewis, E. Meyerowitz and S. Shotwell for comments on the manuscript. Establishment in culture of pluripotential cells from mouse embryos

M. J. Evans* & M. H. Kaufman†

Departments of Genetics* and Anatomy†, University of Cambridge, Downing Street, Cambridge CB2 3EH, UK

Pluripotential cells are present in a mouse embryo until at least an early post-implantation stage, as shown by their ability to take part in the formation of chimaeric animals1 and to form teratocarcinomas2. Until now it has not been possible to establish progressively growing cultures of these cells in vitro, and cell lines have only been obtained after teratocarcinoma formation in vivo. We report here the establishment in tissue culture of pluripotent cell lines which have been isolated directly from in vitro cultures of mouse blastocysts. These cells are able to differentiate either in vitro or after innoculation into a mouse as a tumour in vivo. They have a normal karyotype.

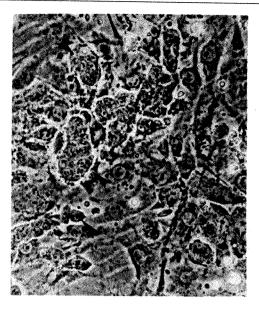

Fig. 1 Groups of pluripotential embryo cells (arrowed) growing in monolayer culture on a background of mitomycin C-inhibited STO cells. The isolation of a definite cell line from a blastocyst takes only ~3 weeks and the pluripotential cell colonies are visible within 5 days of passage. We have had 30% yield of lines from blastocysts in one experiment. Two of the lines have been rigorously cloned by single-cell isolation but most were only colony-picked—this makes no difference

Previous attempts to obtain cultures of pluripotential cells directly from a mouse embryo have been unsuccessful3. although cells with a similar appearance have been reported to be present transiently^{5,6}. We considered that success might depend on three critical factors: (1) the exact stage at which pluripotential cells capable of growth in tissue culture exist in the embryo; (2) explantation of a sufficiently large number of these precursor cells from each embryo; and (3) tissue culture in conditions most conducive to multiplication rather than differentiation of these embryonic cells. These considerations have been discussed at greater length elsewhere. An indication of the optimal stage of embryonic development might be gained by a comparison of the properties of embryonic cells at various stages with established cultures of embryonal carcinoma (EC) cells. Cell-surface antigen expression and the patterns of protein synthesis revealed by two-dimensional electrophoresis have suggested that neither the cells of the 62-day ectoderm nor those of the $3\frac{1}{2}$ -day inner cell mass show homology with EC cells, but that epiblast cells of the early post-implantation embryo at $5\frac{1}{2}$ days post coitum may do so⁸ (the day of finding coital plug is termed day $\frac{1}{2}$). Cells from embryos of an early post-implantation stage seem to be the best candidates for direct progenitors of pluripotential cells in culture. As these embryos are difficult to isolate, and as the cell number in the isolated epiblast is small, we chose an alternative route to obtain embryo cells at this stage of development.

Mouse blastocysts may be induced to enter a state of diapause just before implantation. This delay in implantation depends on the maternal hormonal conditions, and may be induced experimentally by ovariectomy at an appropriate stage⁹. Embryos in implantational delay hatch from the zona but remain free-floating in the uterine lumen. A gradual increase in cell number occurs 10, and the primary endoderm may be formed but no further development takes place until implantation occurs, under the control of hormonal stimuli.

129 SvE mice were caged in pairs and examined for mating plugs each morning. They were ovariectomized on the afternoon of day $2\frac{1}{2}$ of pregnancy, injected subcutaneously with 1 mg Depo-Provera (Upjohn), and delayed blastocysts were recovered 4-6 days later. The blastocysts were cultured intact in

groups of about six embryos in small drops of tissue culture medium under paraffin oil on tissue culture plastic Petri dishes for 4 days. The blastocysts attached within 48 h and the trophectoderm cells grew out and differentiated into giant trophoblast cells. The inner cell mass cells subsequently developed into large egg cylinder-like structures, with a group of small round cells surrounded by endodermal cells growing attached to the Petri dish. The egg cylinder-like structures were picked off the dish, dispersed by trypsin treatment and passaged on to gelatinpretreated Petri dishes containing mitomycin C-inactivated STO fibroblasts. All culture was carried out in Dulbecco's modified minimal essential medium supplemented with 10% fetal calf serum and 10% newborn calf serum. The cultures were examined daily and passaged by trypsinization every 2-3 days. Actively proliferating colonies of cells closely resembling EC cells were apparent from an early stage. These colonies were picked out, passaged and mass cultures grown. The cell cultures had the appearance and general growth characteristics of feeder-dependent EC cells (Fig. 1).

The embryos used to initiate these cultures are from normal 129 SvE strain mice, that is, from the same strain of mice as many EC cell lines, in particular those grown in this laboratory. Therefore it was important to exclude any possibility of contamination of these cultures with EC cells from established cell lines. Cell cultures were established from different embryos in three separate experimental series, but the best indication of their separate identity came from their karyotype. Cultures were initiated from 6-12 embryos, thus it might be expected that both male and female cells should be present. None of the 129 embryonal carcinoma cell lines in this laboratory have a normal karyotype, and, in particular-in common with most available embryonal carcinoma cell lines—they do not contain a Y chromosome. These embryo-derived cells have a completely normal karyotype. An XY karyotype is shown in Fig. 2. Three additional cell lines have been analysed; two of these are normal 40XX and one is normal 40XY. We have termed these directly embryo-derived cells EK to distinguish them from EC cells. EK cells grow rapidly in culture and have been maintained for over 30 passages in vitro.

Cultures of EK cells were collected by trypsinization, and $\sim 10^6$ cells injected subcutaneously into the flank of syngeneic male mice. Tumours grew in all cases, and histological examination of these revealed that they were teratocarcinomas. When the EK cells were passaged without feeder cells they formed embryoid bodies which, when kept in suspension, became cystic.

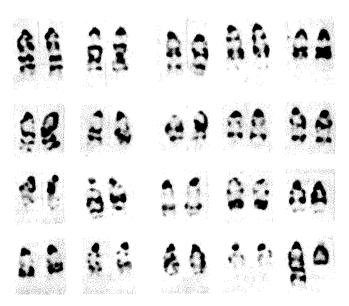

Fig. 2 Karyotype of an embryo-derived pluripotential cell line, 40XY. Over 80% of the spreads of this clonal line possessed 40 - chromosomes and had a clearly identifiable Y chromosome.

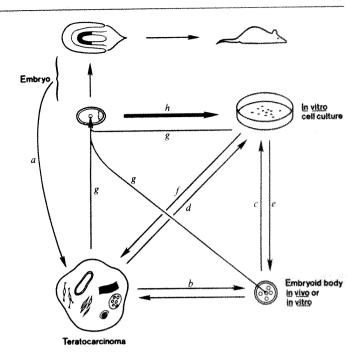

Fig. 3 Inter-relationships of cell lines, teratocarcinomas and embryoid bodies with normal mouse embryos. Arrows indicate routes of cell transfer: a, formation of teratocarcinoma by ectopic implantation of embryos; b, formation of embryoid bodies from teratocarcinoma and vice versa; c, derivation of cell culture from embryoid bodies; d, cell culture obtained directly from solid tumours; e, differentiation to embryoid bodies from culture; f, formation of solid tumours on reinjection of cells from culture; g, transfer of embryonal carcinoma cells either from cell culture or from the core of an embryoid body or from a solid tumour back to a blastocyst. All these procedures may result in chimaerism of the resulting mouse; h, the missing link supplied here.

Embryoid bodies allowed to attach to a Petri dish spread out and differentiated in the usual way into a complex of tissues. Preliminary observations indicate that, like early ectoderm cells of the mouse embryo and EC cells, EK cells carry the cell-surface antigens recognized by M1-22-25 (Forssman)^{8,11} and anti-I Ma (lacto-N-iso-octaosyl ceramide)^{12,13} and also that two dimensional gel electrophoretic separations of their proteins very closely resemble those of the EC cell line PSMB.

We have demonstrated here that it is possible to isolate pluripotential cells directly from early embryos and that they behave in a manner equivalent to EC cells isolated from teratocarcinomas. The network of inter-relationships between the mouse embryo and pluripotential cells derived from it has previously lacked only the direct link between the embryo and cells in culture for completion. We have now demonstrated this (Fig. 3).

Teratocarcinoma cells are now being widely used as a model for the study of developmental processes of early embryonic cell commitment and differentiation. Their use as a vehicle for the transfer into the mouse genome of mutant alleles, either selected in cell culture or inserted into the cells via transformation with specific DNA fragments, has been presented as an attractive proposition. In many of these studies the use of pluripotential cells directly isolated from the embryos under study should have great advantages. We have now shown that these EK cell lines are readily established from cultures of single blastocysts and so far have 15 lines of independent embryonic origin, some of which have been isolated from non-129, outbred mouse stocks. We are now studying the chimaeric mice formed from these cells.

We thank Mrs A. Burling for technical assistance and Dr E. P. Evans for advice regarding karyotype analysis. M.J.E. and M.H.K. were supported by the MRC; M.J.E. also received support from the Cancer Research Campaign.

Stage-specific embryonic antigen involves $\alpha 1 \rightarrow 3$ fucosylated type 2 blood group chains

There is much interest in developmentally regulated molecules which may have function in cell interactions and sorting during embryogenesis and differentiation. Numerous antisera have been raised which detect antigens that are expressed in early embryonic cells and become restricted during differentiation, being expressed in only a minority of adult cells (reviewed in refs 1-3). The precise antigenic determinants recognized by such antisera have not been defined. However, studies using a hybridoma antibody against mouse spleen cells⁴ and monoclonal autoantibodies of patients with cold agglutinin disease⁵ have shown that two defined carbohydrate antigen systems, the Forssman and the Ii antigens, have stage-specific expression in early mouse embryos. We now describe evidence that the stage-specific embryonic antigen SSEA-1 (ref. 6) involves the carbohydrate sequence

Gal
$$\beta$$
1 \rightarrow 4GlcNAc \uparrow 1.3 Fuc α

This determinant is formed by $\alpha 1 \rightarrow 3$ fucosylation of blood group I or i antigens which are branched or linear oligosac-charides, respectively⁷⁻⁹, built of Gal β 1 \rightarrow 4GlcNAc units and known as type 2 precursor chains 10 of the major blood group antigens. Thus, we introduce the concept of simple glycosylation changes as a basis for stage-specific expression of embryonic antigens.

A relationship between the stage-specific embryonic antigen, SSEA-1, and blood group I antigen was suggested by: (1) some similarities in the distribution of these two antigens in early post-implantation embryos and teratocarcinomas^{5,11}, and (2) the reactivities of anti-I and -SSEA-1 reagents with a glycosphingolipid fraction of erythrocytes¹². Subsequent immunocytochemical studies (to be described elsewhere) have clearly shown that the two antigens are not identical. Furthermore, in binding assays using radioiodinated blood group Iactive glycoproteins¹³ isolated from sheep gastric mucins and human meconium, the anti-SSEA-1 reagent gave a binding curve only with the latter glycoprotein (Fig. 1).

The specificity of anti-SSEA-1 reagent was further investigated by inhibition assays using blood group substances with known A,B,H,Lewis^a, Lewis^b, I and i activities, some of which are shown in Fig. 1. These substances were clearly divisible into two groups: those with potent inhibitory activities, giving 50% inhibition at 0.3-6 µg ml⁻¹, and those with negligible or weak activities requiring concentrations >100 µg ml⁻¹ for 50% inhibition. Almost all the substances with strong SSEA-1 activity lacked blood group ABH activities but expressed Le^a and/or Ii activities.

The two ovarian cyst glycoproteins with the strongest SSEA-1 activity, designated N-1 10% and F1, contained 8.5% and 1.6% fucose, respectively^{14,15}. In experiments to be described elsewhere, we showed that their reaction with anti-SSEA-1 was abolished by mild acid hydrolysis. Thus, it seemed likely that the SSEA-1 determinant involved fucose residue(s) and that the fucosyl linkage was other than those associated with A, B, H, Lea or Leb activities 10. This agrees with previous evidence for the presence of unusual fucosyl glycopeptides20 in undifferentiated cells of mouse embryos and teratocarcinomas.

Inhibition of binding assays were next performed with chemically synthesized²¹⁻²³ and natural oligosaccharides^{14,24} containing type 1 $(Gal\beta 1 \rightarrow 3GlcNAc)$ or type 2 $(Gal\beta 1 \rightarrow$ 4GlcNAc/Glc) precursor chain¹⁰ sequences (Fig. 2). Whereas Ii-active synthetic tri- and pentasaccharides consisting of type 2 precursor chains were inactive as inhibitors of anti-SSEA-1, several fucose-containing oligosaccharides showed inhibitory activities. The most active inhibitor (ID₅₀ 0.5 nmol) was the oligosaccharide designated N-1 R_L 0.71a, containing a fucosylated type 2 sequence:

$$Gal\beta 1 \rightarrow GlcNAc$$

$$\uparrow^{1.3}$$

$$Fuc\alpha$$

This oligosaccharide was one of several isolated from glycoprotein N-1 after partial alkaline degradation¹⁴. The very poor inhibitory activity of 3-fucosyl lactose indicated that subterminal N-acetyl glucosamine is an important component of

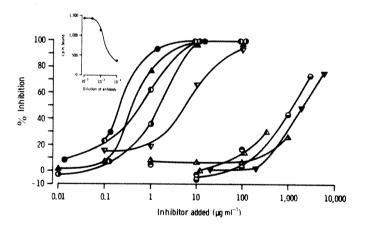

Fig. 1 Double antibody radioimmunoassay using anti-SSEA-1 and 125 I-labelled human meconium. The immunoassay procedure was a modification of that described previously 13. The anti-SSEA-1 reagent 6.11 was ascites fluid from a pristane-primed BALB/c was ascites fluid from a pristane-primed BALB/c mouse injected with antibody-producing hybrid cells. Normal mouse serum, 1:100 dilution, was used as carrier and undiluted rabbit anti-mouse immunoglobulin serum (Dako-immunoglobulins) as second antibody. The binding curve is shown in the inset. Inhibition assays were performed using the anti-SSEA-1 reagent at 1:3,000 dilution. As inhibitors blood group substances of human and animal origins were used. Symbols, blood group activities and designations (the latter in parentheses) of representative samples are given below. The following were human ovarian cyst gly-coproteins: \bullet , Le^aI (N-1 10%)¹⁴; \triangle , Ii (FI)¹⁵; \bullet , Ii (484 ¹³; \blacktriangledown , Le^a (445); \triangle , HLe^b (JS)¹⁶; \ominus , A (438)¹³. Also tested were gastric mucosal glycoproteins from sheep, \triangle , Ii (sheep 1 + 10)¹⁷ and from hog, \blacktriangledown , AH (hog A + H)¹⁸, a glycoprotein-rich extract from human meconium of non-secretor type, ①, Le*Ii (Mec)13 and polyglycosyl ceramides isolated from human erythrocytes, O, HIi (ref. 19).

the SSEA-1 antigenic determinant. The Le^a-active oligosaccharides tested having the type 1-based terminal sequence

were almost 10 times less active than their type 2 isomers. Lacto-N-difucohexaose I (Le^b active), lacto-N-fucopentaose I (H active) and 3-fucosyl lactose were 200-1,000 times less active as inhibitors; 2-fucosyl lactose, lacto-N-tetraose and lacto-N-neotetraose were inactive.

Further investigation is required to determine whether the weak inhibitory activity observed with the Lea-active oligosaccharide represents a cross-reaction or whether it is due to the presence of their type 2 isomers in the preparations tested. It is also of interest to determine whether the 3-fucosyl N-acetyl lactosamine structure is the entire antigenic determinant recognized by anti-SSEA-1 or whether, as with Ii antigens 7-9.2 additional internal structures are involved. A recent observation¹² that a mixture of erythrocyte glycosphingolipids (H4 fraction) with blood group H and I activities precipitates with anti-SSEA-1, indicated that the SSEA-1, H and I antigens might co-exist on the same macromolecules. Glycosphingolipids with 3-fucosyl-N-acetyl lactosamine sequence are known to accumulate in adenocarcinomas26 but it has not been demonstrated on erythrocyte glycosphingolipids of the H1-4 series, although its presence in small amounts has not been completely ruled out (S. Hakomori, personal communication).

Previous studies^{5,27} have shown that the earliest embryo cells of the mouse and similarly, undifferentiated teratocarcinoma cells, express I antigen which is a branched oligosaccharide built of *N*-acetyl lactosamine units^{7,8} as follows:

$$Gal\beta 1 \rightarrow 4GlcNAc\beta 1$$

$${}^{3}Gal\beta 1 \rightarrow 4GlcNAc...$$
 $Gal\beta 1 \rightarrow 4GlcNAc\beta 1$

Presumably, a proportion of these chains become glycosylated with fucose in $\alpha 1 \rightarrow 3$ linkage in the late eight-cell stage, when SSEA-1 activity is first found⁶. At the start of differentiation, i is expressed on visceral endoderm cells in addition to I (ref. 5) and SSEA-1 (refs 9, 11). The i antigen is a linear structure also built of N-acetyl lactosamine units⁹:

$$Gal\beta1 \rightarrow 4GlcNAc\beta1 \rightarrow 3Gal\beta1 \rightarrow 4GlcNAc...$$

Subsequently, during embryogenesis and embryonal carcinoma cell differentiation, several types of differentiated epithelia are found which lack I, i and SSEA-1 activities. A reciprocal increase in blood group H activity has been demonstrated in some of these⁵. The relationship between the I, i, SSEA-1 and H antigens is schematized in Fig. 3. It is now well established that the I and i antigens are masked in the presence of the blood group H-active fucose in $\alpha 1 \rightarrow 2$ linkage to galactose^{9,28} and a similar conclusion can be reached from the present studies, with respect to masking of SSEA-1 antigen by such fucosylation. Alternatively, sialylation may occur at the terminal galactose; in $\alpha 2 \rightarrow 3$ linkage the sialic acid causes partial or complete masking of the I and i antigens^{7,8} and possibly the SSEA-1 antigenic determinants. We can extrapolate further and envisage that, depending on the relative activities of the various glycosyl transferases (and perhaps glycosidases) in individual differentiated tissues, the proportions of these several antigenic determinants will vary. For example, variation in fucosylation might explain the presence of SSEA-1 in some blastomeres but not in others 1-3,6

Thus, simple glycosylation steps involving changes in proportions of linear and branched structures and their fucosylated or sialylated derivatives provide a mechanism for stage-specific appearance and disappearance of antigens. It will be of interest to investigate which of the other various embryonic antigens¹⁻³ that disappear on differentiation reflect subtle glycosylation changes.

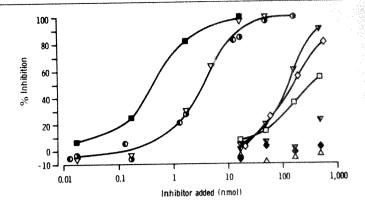

Fig. 2 Inhibition of binding of anti-SSEA-1 to ¹²⁵I-labelled meconium by oligosaccharides. Symbols and structures for the oligosaccharides in order of their inhibitory activies are as follows:

■ Gal
$$\beta$$
1 → 4GlcNAc β 1 → 6?—3 hexenetetrol(s)
↑ 1.3
Fuc α N-1 R_L 0.71a

$$\nabla$$

, Gal β 1 \rightarrow 4GlcNAc β 1 \rightarrow 3al β 1 \rightarrow 4Glc Lacto-N-neotetraose

The following synthetic oligosaccharides²¹⁻²³ were inactive at the highest levels tested shown in parentheses:

$$Gal\beta1 \rightarrow 4GlcNAc\beta1 \rightarrow 3Gal (55 nmol),$$
 $Gal\beta1 \rightarrow 4GlcNAc\beta1 \rightarrow 6Gal (92 nmol),$
 $Gal\beta1 \rightarrow 4GlcNAc\beta1$
 $Gal\beta1 \rightarrow 4GlcNAc\beta1$
 $Gal\beta1 \rightarrow 4GlcNAc\beta1$

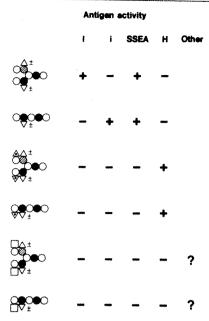

Fig. 3 Schematic presentation of the proposed structure for the SSEA-1 antigenic determinant and its relationship to blood group I, i or H active oligosaccharides and to sialylated structures of undetermined antigenic specificity. Symbols: \bigcirc , $\beta 1 \rightarrow 4$ linked galactose; \bullet , $\beta 1 \rightarrow 3$ linked N-acetyl glucosamine; \emptyset , $\beta 1 \rightarrow 6$ linked N-acetyl glucosamine; \triangle , $\alpha 1 \rightarrow 3$ linked fucose; \triangle , $\alpha 1 \rightarrow 2$ linked fucose; \Box , $\alpha 2 \rightarrow 3$ linked sialic acid; \pm implies optional substitution with $\alpha 1 \rightarrow 3$ linked fucose, such that in the absence of other peripheral monosaccharides, the I, i or the SSEA-1 antigenic determinants are expressed. It is not known whether the $\alpha 1 \rightarrow 2$ fucosylation or the sialylation steps precede or follow the $\alpha 1 \rightarrow 3$ fucosylation of these precursor chains.

The biological significance of the orderly changes of these and the major blood group antigens ABH (ref. 29) during development and differentiation is unknown. If these various carbohydrate sequences function as recognition structures involved in cell interactions and tissue organization, it can be anticipated that there will be a progressively increasing list of complementary molecules (endogenous lectins) specifically reactive with them. From the present studies it can be predicted that a 3-fucosyl N-acetyl lactosamine-mediated recognition system, analogous to the previously described lectin-like compound on hepatocytes³⁰, is operating at the embryonic cell surface, and it is tempting to speculate that such a lectin may be involved in the process of compaction. This occurs at the eight-cell stage of the mouse embryo when blastomeres become tightly associated with each other and undergo substantial changes in their organization during differentiation³¹. Thus, there is now a need to investigate the significance of different carbohydrate structures and lectins^{32,33} on mammalian embryonic cells. They may be involved in sugar-protein interactions which are crucial and specific for phenomena as varied as receptor-mediated uptake of circulating glycoproteins 30,34,35 and the homing of enzymes to appropriate intracellular compartments 34,36.

We thank Drs E. A. Kabat, W. M. Watkins, C. Augé, S. David, A. Veyrières and J. Koscielak for providing oligosaccharides and blood group substances, Mrs Jean Picard for serological assessment of meconium extracts, Dr Peter W. Andrews for helpful discussions, and Mrs M. Moriarty for secretarial assistance. H.C.G. is a fellow of the Arthritis and Rheumatism Council, UK, and A.K. and M.J.E. are supported by the Cancer Research Campaign, UK. This study was supported in part by the US grants TSH NIH CA 18470, CA-10815, HD-12847 and NSF grant PCM-7816177.

Note added in proof: Further studies to be described elsewhere (E. F. Hounsell, H. C. Gooi and T. Feizi, in preparation) have shown that the inhibition of anti-SSEA-1 by the type 1 oligosaccharide, lacto-N-fucopentaose II, is due to the presence of the type 2 isomer, lacto-N-fucopentaose III, in this preparation. Erythrocyte membrane sidedness in lectin control of the Ca²⁺-A23187-mediated diskocyte echinocyte conversion

Richard A. Anderson & Rex E. Lovrien

Biochemistry Department, Gortner Laboratory, University of Minnesota, St Paul, Minnesota 55108, USA

Increasing the cytoplasmic calcium concentration of human erythrocytes with ionophore A23187 drives the transformation from diskocyte to echinocyte morphology¹. This transformation is closely linked to the intracellular ATP level, which drops when calcium is introduced across the membrane^{2,3}. The echinocyte morphology reverts to the diskocyte after restoration of normal ATP and calcium levels4.5. ATP control of cell morphology is thought to depend on the action of a protein kinase and phosphatase which reversibly modify the membrane cytoskeleton 6-9. The cytoskeleton in turn is in contact with the outside membrane surface via transmembrane proteins 10-11. We show here that binding of the lectin, wheat-germ agglutinin (WGA), to the erythrocyte membrane surface blocks the morphological conversions diskocyte = echinocyte in both directions. WGA seems to work via a mechanism involving the transmembrane glycoprotein, glycophorin 13,14.

Wheat-germ agglutinin was used as a convenient tool to control in a reversible way the morphological conversion initiated by Ca²⁺-A23187 on the cytoplasmic side. The internal echinocytic reactions initiated by Ca²⁺-A23187 are not blocked by WGA binding to the membrane; instead they go to completion and are 'stored' until finally expressed, as a morphological change, when WGA is displaced from the membrane.

Fig. 1 Control of human erythrocyte morphology by wheat germ agglutinin (WGA) on the cell's outside surface in relationship to internal calcium loading and cell metabolism. Final erythrocyte concentration for sequence I is $1 \times$ 10⁷ cells ml⁻¹ . Buffer (mM): 10 KC1, 130 NaCl, 2 MgCl2, 15 Tris, pH 7.4, 25 °C. Erythrocytes were drawn and washed as described before 14. In sequence I the concentration of WGA is 2 µg ml⁻¹; this results in 18×10⁵ molecules bound per cell. In reaction (2), 0.2 mM Ca² and 5 µM A23187 were added, giving the final cytoplasmic calcium concentration at equilibrium of 0.4 mM. Addition of ionophore without calcium caused no added morphological change. Calcium influx into the cell was 50% complete after 30 s, 80% complete

Sequence I

Co NAG WGA

after 60 s and 100% complete after 100 s. The influx was followed using 45 Ca $^{2+}$ (ref. 15). The binding of WGA to the cell did not change the flux of calcium across the membrane or the final cytoplasmic calcium concentration. Calcium was then withdrawn from the cell using 2 mM EGTA, leaving $< 10^{\circ}$ µ, μ , 150 s after addition of EGTA. Lectin was displaced from the membrane by addition of 30 mM NAG. The unbinding was followed with 125 I-WGA 14 , and was complete ($< 2 \times 10^5$ molecules per cell) within 30 s of addition of NAG. In sequence II, diskocytes are converted to eckinocytes using the above conditions. In reaction (2) calcium was removed with 2 mM EGTA and ionophore A23187 with a 0.3% bovine serum albumin wash. The red cells were > 90% echinocytes at this point, but upon re-energizing with 5 mM glucose and 2 mM inosine [reaction (3)], 95% of the cells reverted to diskocytes within 2 h. In reactions 4–6, the cell concentration was lowered to 2×10^6 cells per ml to avoid lectin-induced agglutination during the 2-h glucose—inosine incubation. The WGA concentration was 1 μ g ml $^{-1}$, with 20×10^5 molecules bound per cell.

The sequences of morphological changes are illustrated in Fig. 1. Figure 2 shows scanning electron microscope photographs of red cells in the critical stages of the reactions.

For the experiments of sequence I (Fig. 1), WGA was added to diskocytes such that the amount bound, ν_{WGA} , was 1.8×10^6 molecules of WGA per cell. This amount did not produce any change in cell morphology, as was expected ¹⁴. When the cytoplasmic calcium concentration was increased, using 0.2 mM Ca²⁺ and 5 μ M A23187, the cells with this level of bound lectin completely retained their normal diskocyte morphology. However, erythrocytes treated identically, but without lectin, lapsed to the echinocyte morphology within a few minutes. Figure 2a and b contrasts lectin-protected and unprotected cells.

The lectin does not control morphological conversion by blocking transport of calcium into the cell by ionophore A23187 because when the Ca²⁺ flux into the cell was quantified using ⁴⁵Ca²⁺ (ref. 15), both the rate of Ca²⁺ influx and the final cytoplasmic concentration of calcium were found to be identical for cells with bound lectin, and control cells.

WGA is rapidly displaced from protected cells by N-acetyl-glucosamine (NAG). Reaction (3) of sequence I shows that within 30 s of addition of NAG to lectin-protected Ca^{2+} -loaded diskocytes, the lectin was displaced and the diskocyte \rightarrow echinocyte conversion completed. The velocity of this reaction was greater by an order of magnitude than that of the conventional Ca^{2+} -A23187-driven conversion (see Fig. 3), indicating that the erythrocytes were already calcium loaded when NAG was added.

Reaction (2) of sequence I shows that WGA completely blocks the echinocyte effects of Ca^{2+} -A23187. Reactions (4) and (5) show that the lectin does not block internal reactions initiated by Ca^{2+} . In reaction (4), EGTA was used to remove cytoplasmic Ca^{2+} . Using $^{45}Ca^{2+}$, removal of Ca^{2+} was shown to be complete (within experimental error of the measurement of cytoplasmic Ca^{2+} which is $\pm 10 \,\mu\text{M}$) within 150 s of addition of EGTA. The products of reaction (4) are diskocytes which have had Ca^{2+} -A23187 influxed, then completely removed, while fully protected by WGA. However, when WGA is displaced by NAG, as shown in reaction (5), the Ca^{2+} -free diskocytes

immediately change to echinocytes. Thus the internal reactions initiated by Ca²⁺-A23187 are not erased by removal of Ca²⁺, but their final expression, formation of echinocytes, is permitted only when the external lectin is removed.

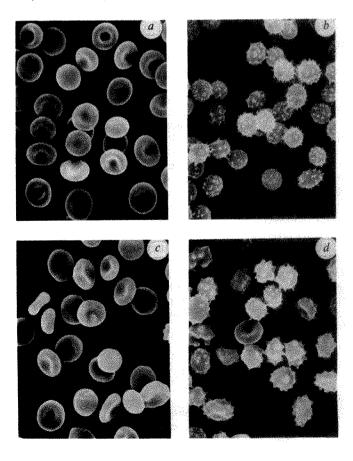

Fig. 2 Scanning electron micrographs of erythrocytes from stages indicated by the letters a, b, c and d in Fig. 1. Scale bar, $5 \mu m$.

The effects of calcium on the cell morphology are reversible if the initial calcium concentration is < 0.5 mM and the incubation time with calcium < 15 min. In these conditions cytoskeletal cross-linking 16,17 by endogenous transglutamidase or disulphide coupling 5 does not occur to a significant extent. This is supported by the fact that the echinocyte morphology is reversed on restoration of normal calcium and ATP levels. Calcium also activates an endogenous phospholipase C which results in the hydrolysis of phosphotidylinositol and the accumulation of 1,2-diacyglycerol 18,19 . In our conditions < 0.4% ($< 10^6$ molecules per cell) of the phospholipids would be hydrolysed 19 . It is unlikely that this small amount of 1,2-diacylglycerol would effect a morphological conversion 24 .

The forward and reverse rates of the diskocyte \rightleftharpoons echinocyte conversion in the absence of WGA and the profound decrease in these rates effected by the lectin are shown in Figs 3 and 4. The ordinate value in these figures, r, is the fraction of cells which are echinocytes; at r = 0, all cells are diskocytes.

Reaction (1) of sequence II represents a conventional diskocyte \rightarrow echinocyte conversion by Ca²⁺-A23187. When this conversion is 100% complete, the Ca²⁺ is removed by EGTA and the ionophore A23187 by serum albumin. If glucose and inosine are then added to allow regeneration of ATP, these calcium-unloaded echinocytes revert slowly to the diskocyte form. At least 95% diskocytes (r = 0.05) are obtained after 2 h.

In reaction (4) WGA is used to control the Ca²⁺-A23187-produced echinocytes. If lectin is added to calcium-unloaded echinocytes followed by incubation in glucose for 2 h (the time necessary for completion of the conventional echinocyte →diskocyte conversion), the cell morphology does not change from the echinocyte. If the lectin is then displaced with NAG, the echinocyte → diskocyte conversion proceeds to completion within seconds. It is clear that the reactions needed to erase the impact of Ca²⁺-A23187 on the membrane take place by the end of the 2-h incubation with metabolite. Thus displacement of WGA from echinocytes, which have been emptied of Ca²⁺-A23187 and re-energized, causes a return to the diskocyte that is much more rapid than the conventional reversal in reaction (3).

The diskocyte ≠echinocyte conversion is the result of a number of molecular events within the membrane. Increased cytoplasmic calcium activates internal reactions, which drive the change in cell shape. The data presented in Figs 3 and 4 indicate that the internal reactions for the diskocyte ≠echinocyte morphological conversions are not blocked by lectin binding to the outside of the membrane. Instead lectin binding to one membrane component, which is crucial in the sequence of molecular events, blocks this component's participation in the sequence or pathway leading to morphological conversion, thereby completely blocking the conversion.

The receptor for WGA on the human erythrocyte is the major sialoglycoprotein, glycophorin^{13,14}. WGA binds to the sialic acid groups of glycophorin; when these groups are removed, lectin binding and control of cell morphology are eliminated¹⁴. Glycophorin is a transmembrane protein and is thought to be associated with band III within the membrane¹¹. It can thus interact with the cytoskeleton via the linkage band III–ankyrinspectrin^{10,12}. Accordingly, WGA may influence the cytoskeleton and cell morphology, via the transmembrane proteins, in the following way:

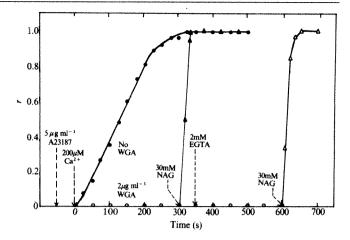

Fig. 3 Time course of the diskocyte → echinocyte conversions from sequence I, Fig. 1. r, Fraction echinocytes. Points lying on the abscissa (r = 0) represent WGA-protected diskocytes.

The existence of a cross-linking mechanism whereby the lectin randomly cross-links glycophorins to form an exocytoskeleton seems unlikely as: (1) freeze-fracture electron microscopy has shown that lectins do not cause clustering of receptors on intact cells^{20,21}, (2) the glycoprotein receptors are uniformly distributed in the membrane, ~200 Å apart² (3) the carbohydrate binding sites on WGA are 40 Å apart²⁵ and thus WGA could not span the distance separating the glvcophorins. It is more likely that each WGA binds specifically to one glycophorin molecule, or, perhaps, to a dimer. Support for this view comes from work with peanut lectin, which can control change of shape of the desialated erythrocyte. Peanut lectin binds to desialoglycophorin with high specificity²³ and, at a concentration of 3×10^5 molecules bound per cell, completely blocks the diskocyte → echinocyte conversion. As there are only about 6×10^5 monomers of glycophorin per cell¹⁴, it is very

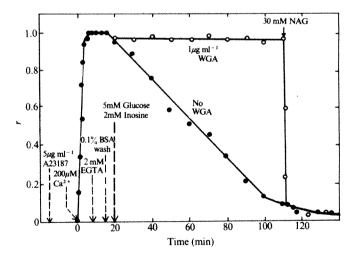

Fig. 4 Time course of the echinocyte → diskocyte conversions from sequence II, Fig. 1.

Metabolism Cytoskeletal Diskocyte External Transmembrane Internal glycophorin ↔ control of 1 glycophorin Lectin → glycophorin → cytoskeleton cell shape Echinocyte saccharide interaction Ca2+

unlikely that random cross-linking takes place with such a small amount of lectin bound. A more reasonable proposition is that the lectins exert their control of morphology by intramolecular binding to a glycophorin dimer. This is supported by the fact that the molecular ratio of peanut lectin: glycophorin is 1:2 when morphology is completely blocked (R.A.A. and R.E.L. unpublished results).

The transmembrane protein glycophorin is a crucial component in cytoplasmic Ca2+-induced morphological change, and lectins may exert their control of morphology by specifically binding to glycophorin. The 'sidedness' or asymmetric nature of glycophorin enables carefully aimed use of lectins, specific for glycophorin's external carbohydrate, to block the expression of internal biochemical reactions. The indirect action of Ca2+ on the cell cytoskeleton is paramount in this morphology conversion. Thus it is likely that glycophorin-cytoskeletal contact is also important in this morphological conversion.

A new protein that gels F actin in the cell cortex of Dictyostelium discoideum

John Condeelis & Jeffrey Salisbury

Department of Anatomy, Albert Einstein College of Medicine, Bronx, New York 10461, USA

Keigi Fujiwara

Department of Anatomy, Harvard Medical School, Boston, Massachusetts 02138, USA

It is thought that the dense actin filament networks found in the cortex of many cell types 1-4 might account for the gelled consistency of the cortex⁵ and the exclusion of other organelles from this region of the cytoplasm⁶⁻⁸. We now demonstrate that a new actin-binding protein from Dictyostelium that gels actin in vitro is concentrated in the cell cortex, suggesting that this protein, in association with actin, accounts for the gel-like properties of this region of the cell.

Cell extracts from the amoeboid stage of the cellular slime mould Dictyostelium discoideum contain protein factors that gel actin filaments in vitro9. We have recently purified to homogeneity one of these gelation factors that has a molecular weight of 120,000 (120K)¹⁰. It is a soluble, trypsin-sensitive and carbohydrate-free protein that increases the viscosity and sedimentation rate of F actin, inhibits the actin-stimulated Mg²⁺-ATPase activity of myosin and nucleates actin filament assembly in vitro 10. The interaction of this actin-binding protein with F actin is not inhibited by millimolar ATP or micromolar calcium. Electron microscopy demonstrates that this protein promotes both side-to-side and end-to-side interactions between actin filaments in vitro 8,10

To ascertain the function of this protein in vivo we have used the indirect immunofluorescence technique to determine its location in spreading and migrating cells. Antisera were raised against purified native 120K protein in rabbits and characterized as monospecific by double diffusion and immunoelectrophoresis in agar¹¹ (Fig. 1). Dictyostelium amoebae were cultured in suspension in HL5¹⁰, washed in 20 mM KCl, 1 mM CaCl₂, 2 mM

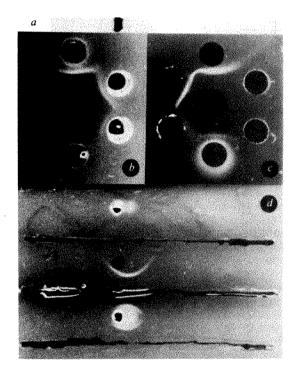

Fig. 1 The 120K protein was purified from *Dictyostelium* amoebae as described elsewhere ¹⁰. a Shows SDS-polyacrylamide gel electrophoresis of the purified antigen. Rabbits were immunized with native 120K protein by subcutaneous injection of antigen in complete Freund's adjuvant and boosted once with antigen in incomplete Freund's adjuvant 4 weeks after initial immunization. Antiserum was characterized using double immunodiffusion in 1% agarose 11. b Shows result with antiserum in the centre well with a clockwise progressive twofold dilution of native 120K protein in the outer wells. c Shows the result with antiserum in the centre with outer wells filled with the following, clockwise from the top: a complex of 95,000 MW protein-120K protein-actin 10; 95,000 MW protein alone; 95,000 MW protein plus actin; whole cell extract; 1/5th dilution native 120K protein; native 120K protein. In both cases single precipitin arcs result showing monospecificity and fuse to demonstrate immunological identity. No reaction was found in samples containing actin or 95,000 MW protein, the other major actin-binding protein found in Dictyostelium 9.10. d, Immunoelectrophoresis was performed as described previously in 1% agarose 11. Wells from top to bottom contain cell extract, native 120K protein and cell extract. Troughs from top to bottom contain pre-immune serum, antiserum to 120K protein and antiserum to 120K protein. A single precipitin line with the same electrophoretic mobility is formed against 120K protein and the cell extract.

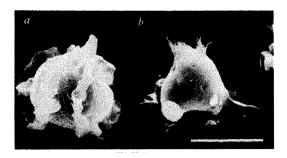

Fig. 2 Scanning electron micrographs of spreading (a) and migrating (b) amoebae on poly-L-lysine. Cells were prepared for microscopy by fixation in 2% glutaraldehyde in 40 mM sodium phosphate pH 7.0 for 10 min, dehydrated in ethanol and critical point dried against CO₂. Scale bar, 10 μM.

MgSO₄ and 40 mM sodium phosphate pH 6.4 and allowed to spread and migrate on poly-L-lysine-coated coverslips. In these conditions, when the cells first make contact with the adhesive surface, they become flattened against the substrate on the bottom and proceed to throw ruffles from the surface back over the cytoplast, which remains rounded (Fig. 2a). The cells then progressively flatten and begin to migrate by sending out large flat ruffles or pharopods (Fig. 2a). In randomly migrating cells such as those shown here the pharopods are usually extended from all sides of the cell with only one or two gaining dominance at the leading edge during net locomotion (Fig. 2b). Migrating cells usually remain slightly rounded in the cytoplast region which contains the nucleus and other organelles, even when exhibiting rapid migration. At no stage during spreading or locomotion are stress fibres or large microfilament bundles observed within these cells in either the light or electron microscope, respectively8.

Immunofluorescence for 120K protein in cells undergoing various stages of spreading and migration on poly-L-lysine is shown in Fig. 3. All the cells have bound antiserum and exhibit at least one of two types of fluorescence: weak diffuse fluorescence which seems to be distributed throughout the cytoplasm exclusive of the nucleus, and strong peripheral fluorescence which is concentrated in the cell cortex, ruffles and pharopods. In spreading cells (Fig. 3c), ruffles at both the cell margin and those thrown back over the cytoplast stain for the presence of 120K protein. In migrating cells (Fig. 3d), 120K protein is concentrated primarily in pharopods that extend randomly from the cell margin. In both cases a thin rim of fluorescence is usually seen around most of the periphery of the cell.

To determine whether 120K protein was present in mammalian cells, human (HeLa) and rat kangaroo (Ptk-2) tissue culture cells were fixed, permeabilized and stained with antiserum against 120K protein as described above. None of these cells demonstrated immunofluorescence for the protein.

The concentration of 120K actin-binding protein in structures associated with the cell periphery is analogous to the immunofluorescence localization in the cell cortex of macrophage actin-binding protein 12 and filamin 13 in macrophages and cultured fibroblasts, respectively. The localization of 120K protein in the cell cortex, ruffles and pharopods of *Dictyostelium* is quite similar to that of macrophage actin-binding protein in lung macrophages 12 but less similar to the location of filamin in cultured fibroblasts, where this protein is also found in stress fibres. This latter difference might be due more to the absence of actin-containing stress fibres from *Dictyostelium* amoebae and macrophages than to dissimilarities in function between 120K protein and filamin.

The properties of purified 120K protein in vitro and its concentration in the cell cortex in situ suggest possible functions for this protein in vivo. The location of 120K protein in the cell corresponds well with that of actin determined by immunofluorescence¹⁴ and electron microscopy⁸. This protein

cross-links and gels filamentous actin and hence may be required with actin for the formation of the cortical gel long known to be present in amoeboid cells⁵. The presence of weak fluorescence for 120K protein throughout the cytoplasm of *Dictyostelium* amoebae suggests that small amounts of the protein in association with actin may also account for the presence of the diffuse filamentous network seen throughout the cytoplast⁸. The concentration of 120K protein in ruffles and pharopods indicates that cytoplasm within these structures has an increased potential for the formation of a rigid actin gel but does not prove that the cytoplasm in this region is gelled continuously, because gels formed from 120K protein and actin *in vitro* are readily solated by micromolar Ca²⁺ in the presence of 95K protein^{6,9,10}.

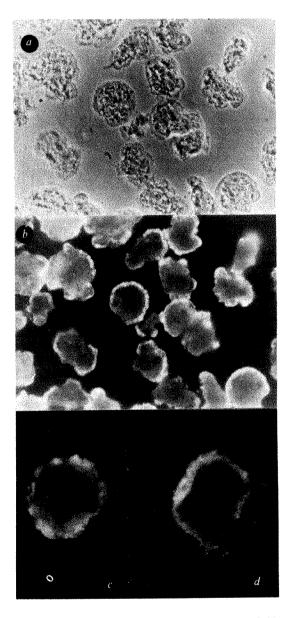

Fig. 3 Light microscopy of amoebae on poly-L-lysine. Cells were fixed in 3.7% formaldehyde in 0.85% NaCl, 10 mM sodium phosphate pH 7.2 for 10 min, permeabilized in -20° C acetone and stained with rabbit antiserum against 120K protein followed by goat anti-rabbit IgG conjugated to rhodamine (Cappel). Controls were as follows: pre-immune serum in place of antiserum against 120K protein, deletion of immune serum before staining with goat anti-rabbit IgG, cells fixed but not permeabilized with acetone, use of antiserum preabsorbed with native 120K protein. Staining was not detected in any of these controls. a, Phase and b, fluorescence of cells permitted to spread and migrate on poly-L-lysine; c, spreading cell, and d, migrating cell at higher magnification. a and b, $\times 1,200$; c and d, $\times 2,500$.

This protein also nucleates assembly of actin filaments, thereby promoting end-to-side filament attachments resulting in branched filaments which are frequently observed in the cortex of Dictyostelium in situ^{4,8}. Concentration in the cell cortex of actin nucleation activity associated with 120K actin-binding protein would have substantial significance in the generation of new actin filaments in this region of the cell during sol-gel transformations and pseudopod extension, and might result in the production of large numbers of free actin filament ends which could be used to advantage by the cell to establish membrane-filament attachments⁶.

T cell-dependent IgA anti-polysaccharide response in vitro

Park E. Trefts, Denis A. Rivier & Martin F. Kagnoff

Department of Medicine, University of California at San Diego, La Jolla, California 92093, USA

The induction in mice of humoral antibody to purified polysaccharides, such as dextran B1355, dextran B512 and other bacterial capsular materials, is generally regarded as being thymus independent¹⁻⁵, that is, not requiring conventional carrier-specific T-cell help6. Such responses are largely immunoglobulin M (IgM), often transient although occasionally cyclic, and there is little evidence of immunological memory The selective formation of an IgG response to polysaccharides or haptenated polysaccharides (for example, dextran B512, dinitrophenol (DNP)-Ficoll) has also been characterized as thymus independent 12,13. Recent reports have indicated that the murine IgG response to such antigens is restricted largely to the IgG₃ subclass ^{14,15} although lesser amounts of other IgG subclasses have been reported after stimulation with thymusindependent antigens such as DNP-Ficoll and DNP-Levan 16,17 In the latter study, T cells were shown to influence certain IgG subclass responses to haptens on a thymus-independent carrier¹⁷. Here we report that BALB/c mice produce a substantial IgA anti- $\alpha(1,3)$ dextran B1355 response in vitro that is highly T-cell dependent and age-dependent. This finding represents a significant departure from previous observations and may have particular relevance for mucosal immunity. It also suggests the need for a re-evaluation of the induction and regulation of anti-polysaccharide antibody responses.

To study the induction and regulation of the Igh-1^a allotypelinked anti- $\alpha(1,3)$ antibody response to the purified polysaccharide dextran B1355 (43% $\alpha(1,3)$ and 57% $\alpha(1,6)$ glucan linkages) we used Mishell-Dutton in vitro culture methods¹⁸. As shown in Table 1, substantial IgA anti- $\alpha(1,3)$ dextran responses were seen only when spleen cells were obtained from old (10-17-month-old) BALB/c mice. In contrast, spleen cells from

young (4-month-old) or old (12-month-old) BALB/c (Igh-1") mice could be stimulated by dextran B1355 to produce IgM anti- $\alpha(1,3)$ dextran responses over a 3-5-day culture period. Similar results (not shown) were obtained in cultures using mesenteric lymph node (MLN) cells. The IgM and IgA antidextran B1355 antibody in spleen and MLN cultures shared idiotypic determinants with the two well-characterized anti- $\alpha(1,3)$ glucan myelomas, MOPC 104E (IgM λ_1) and J558 $(IgA \lambda_1)^{19}$ as determined in specific inhibition studies with anti-J558 or anti-MOPC 104E antiserum.

To determine whether the absence of the IgA anti- $\alpha(1,3)$ dextran response in spleen or MLN cells from younger mice was due to cell-mediated suppression, we compared the responses in cultures containing young, old or age-mixed spleen or MLN cells. Cells from young mice did not suppress the anti-dextran response of cells from old mice (see Fig. 1).

The IgA anti- $\alpha(1,3)$ dextran response was markedly T-cell dependent (see Fig. 2). Thus, anti-Thy 1.2 and complement treatment ablated the in vitro IgA anti- $\alpha(1,3)$ dextran response in spleen and MLN cells and such responses were totally reconstituted by the addition of T cells.

To clarify the nature of the T-cell regulation of the IgA response, we used dextran B1355 derivatized with trinitrophenol (TNP)-lysine (TNP-dex)20 as an in vitro antigen. Our experiments demonstrate that the IgA response after stimulation with TNP-dex was limited to dextran $\alpha(1,3)$ determinants. Both IgA and IgM anti- $\alpha(1,3)$ dextran responses were induced by this antigen (Fig. 3) whereas there was only an IgM response to the TNP determinant in either normal (Fig. 3a) or TNP-protein-primed (Fig. 3b) mice.

The results clearly demonstrate the age-dependence of the in vitro IgA anti- $\alpha(1,3)$ dextran B1355 response in BALB/c mice. Antigen-stimulated cultures from 2-8-month-old BALB/c mice did not produce significant IgA anti- $\alpha(1,3)$ glucan antibody although such cultures were competent in terms of anti-sheep red cell (SRBC) (not shown) and IgM anti- $\alpha(1,3)$ glucan responses. Note that although we did not prime the old mice used in our study, the mice may not be antigenically naive. Polyglucans are ubiquitous antigens in the mammalian digestive tract and the increase in the IgA anti- $\alpha(1,3)$ glucan response in ageing mice may be due to T- and/or B-cell priming with

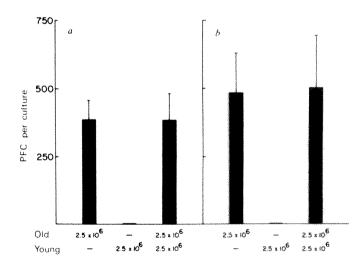

Fig. 1 Failure of lymphoid cells from young BALB/c mice to suppress IgA anti-α(1,3)dextran B1355 response in cultures containing lymphoid cells from old BALB/c mice. Spleen cells (a) or MLN cells (b) from 12-month-old (eld) or 6-8-week-old (young) mice were cultured alone or mixed at a 1:1 ratio, Cultures containing 2.5×10^6 old cells, 2.5×10^6 young cells or 2.5×10^6 old cells and 2.5×10^6 young cells in 0.5 ml were stimulated with optimal concentrations of dextran B1355. Cultures were assayed on day 5. Data represent the mean ± s.e.m. of seven experiments (a) and four experiments (b). Culture conditions were as described in Table 1 legend.

Table 1	Age-dependence and kinetics of the in vitro
	anti-\alpha(1,3)dextran B1355 response

Age of mice (months)	Dextran B1355 (ng per culture)		nse* l cells) IgA				
		Day 3	Day 4	Day 5	Day 3	Day 4	Day 5
	None	9	< 2	< 2	NT	NT	NT†
4	0.1	67	106	16	< 2	< 2	< 2
	1.0	78	111	32	< 2	< 2	< 2
	None	7	< 2	< 2	NT	NT	NT
12	0.1	102	303	99	195	509	391
	1.0	80	259	218	199	449	289

The table shows a representative experiment in which spleen cells from 4- or 12-month-old BALB/c mice were cultured at 2.5×10^6 cells per 0.5 ml in Falcon mutiwell tissue culture plates (no. 3008) and stimulated with 0.1 or 1.0 ng dextran B1355. Culture medium RPMI 1640 containing 10% fetal calf serum (FCS, lot 614 from Gibco), 2-mercaptoethanol (5×10^{-5} M), penicillin (40 U ml^{-1}) and streptomycin (40 µg ml^{-1}) was enriched with 12% cocktail 16. Results are means of duplicate cultures.

* Specific anti- $\alpha(1,3)$ responses were assayed using palmitoyl dextran B1355 coupled to HRBC²¹. IgM and IgA anti-dextran plaques were totally inhibited by dextran B1355 but not by dextran B512 (95% $\alpha(1,6)$ and 5% $\alpha(1,3)$ glucan linkages) added to the plaque-forming cell (PFC) assay²¹. IgG responses, including IgG₃, were not detected using polyvalent and subclass-specific enhancing reagents.

 \dagger NT, not tested. In other experiments, low background levels of IgA anti-dextran PFC (that is, from 10 to 40 PFC per 10^6 cultured cells) were noted regularly in lymphoid cell suspensions derived from mice > 10 months old but not in younger mice.

naturally occurring environmental antigens at mucosal surfaces $^{21-23}$.

We point out that the age at which IgA responses were observed in vitro was considerably delayed compared with our previously reported in vivo results in which responses were seen between 1 and 6 months of age²¹. Because over 95% of the anti-dextran B1355 antibody in vivo and in vitro showed idiotypic determinants that cross-reacted with the two well-characterized myeloma proteins J558 and MOPC104E, we conclude that both systems produce antibodies that are similar or identical. We have no convenient explanation for the differences observed in vivo and in vitro. Cell-mediated suppression does not seem to explain the lack of the in vitro IgA response in young mice (see Table 1), but a relative deficiency of specific T or B cell or the size (that is, molecular weight $\sim 4 \times 10^7$), structural or chemical characteristics of the molecule may explain the fact that immunization with dextran B1355 is less efficient in vitro than in vivo. In addition, differences between the in vitro and in vivo systems may depend on the microenvironment or adherent cell requirements^{24,25} for immunocompetence.

The T-dependence of the in vitro IgA anti- $\alpha(1,3)$ dextran response was striking and confirms our previous in vivo report²¹. Invariably, the removal of T cells from spleen or MLN populations eliminated the IgA anti- $\alpha(1,3)$ response and such responses were restored by the addition of T cells. Moreover, the T-dependent IgA anti- $\alpha(1,3)$ response did not seem to require conventional carrier-specific T-cell help⁶. Thus, with TNP-dextran as an immunogen, we routinely observed IgM and IgA anti- $\alpha(1,3)$ dextran responses and IgM anti-TNP responses in spleen and MLN cultures from unprimed or TNP-proteinprimed mice, whereas such cultures produced no significant IgA anti-TNP response. The specificity of the response for $\alpha(1,3)$ glucan determinants argues against polyclonal activation by dextran in this system²⁶ or a role for IgA isotype-specific T-helper cells²⁷. However, we cannot exclude the possibility that the IgA anti- $\alpha(1,3)$ glucan precursor B cell that responds to T-cell help has special cell-surface determinants or properties that are lacking on normal or TNP-primed precursor B cells. We prefer the interpretation that T-cell help for the IgA anti- $\alpha(1,3)$ dextran response is directed to idiotypic determinants on

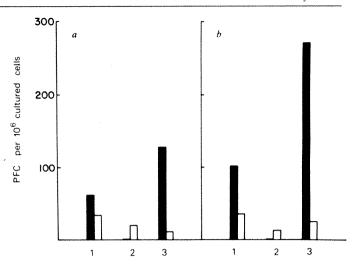

Fig. 2 Representative experiments showing the T-cell dependence of the IgA anti- $\alpha(1,3)$ dextran B1355 response in BALB/c mice. Cultures containing spleen cells (a) or MLN cells (b) were treated with complement alone (1), or anti-Thy 1.2 and complement (2). Additional cultures (3) were treated with anti-Thy 1.2 and complement and reconstituted with MLN which were depleted of B cells before mitomycin C treatment according to a two-step panning procedure $^{37}(a)$ or with mitomycin C-treated spleen cells (b). Cells from triplicate cultures were pooled and assayed on day 5 for specific IgA (solid bars) or IgM (open bars) anti- $\alpha(1,3)$ dextran B1355 responses. Culture conditions were as described in Table 1 legend. IgM anti-SRBC responses in parallel control cultures were totally ablated by anti-Thy 1.2 and complement treatment and restored by T cells (not shown).

anti- $\alpha(1,3)$ glucan antibody associated with the B cell or perhaps accessory cells, and not to $\alpha(1,3)$ determinants on dextran B1355.

Considerable evidence in mice substantiates the ability of antibody directed at specific immunoglobulin idiotypes to suppress or stimulate B cells²⁸⁻³². There is less evidence, however, for T-cell help directed towards idiotypic determinants³³⁻³⁶. Previous studies reported that anti-idiotypic T-cell help for the B-cell response was either antigen-indepen-

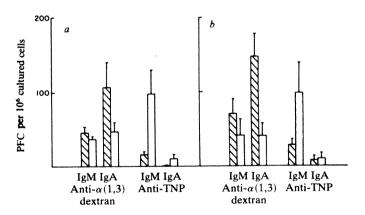

Fig. 3 Specific anti- $\alpha(1,3)$ dextran and anti-TNP responses in spleen or MLN cultures stimulated with TNP-dextran B1355. Cultures containing 2.5×10^6 spleen or MLN cells from 10-17-month-old unprimed BALB/c mice (a) or BALB/c mice primed three times at 1-4-month intervals with TNP-ovalbumin or TNP-keyhole limpet haemocyanin (b) were stimulated in culture with TNP-dextran B1355 (1 ng per culture, hatched bars or 10 ng per culture, open bars). Cultures were assayed 5 days later for specific IgM and IgA anti- $\alpha(1,3)$ dextran B1355 and anti-TNP responses. Data represent the mean±s.e.m. of five experiments with unprimed and six experiments with TNP-primed mice. Culture conditions were as described in Table 1 legend. Control cultures from TNP-protein-primed mice stimulated with TNP on the homologous carrier yielded > 400 IgA anti-TNP PFC per 10^6 cultured cells.

dent³⁵ or required two populations of T cells, one carrier-reactive and the other idiotype-specific³⁴. The striking observation in our study was the antigen-dependence and apparent lack of need for carrier-specific T-cell help for the IgA anti- $\alpha(1,3)$ response in vitro. Thus, T-helper cells are important in the regulation of the immune response to polysaccharide antigens such as dextran B1355. Moreover, anti-idiotypic Thelper cells may play a major part in influencing the induction and regulation of the B-cell repertoire to polysaccharide antigens.

The immune response to such antigens has been difficult to

study, partly because of the lack of a suitable in vitro system for examining the induction and regulation of the antibody response to such antigens. Our study demonstrates the successful application of in vitro culture methods to study the antigen-specific induction of antibody responses to purified dextran Bl355 and seems to represent the first report of an in vitro antigen-induced response by dispersed cell culture to a purified polysaccharide antigen.

Kainate-like neurotoxicity of folates

John W. Olney, Terry A. Fuller & Taisija de Gubareff

Department of Psychiatry, Washington University School of Medicine, St Louis, Missouri 63110, USA

Kainic acid (KA) is one of the most powerful of a group of 'excitotoxic' analogues of the putative neurotransmitter glutamate (Glu) whose neurotoxicity may involve an excitatory mechanism mediated through glutamergic postsynaptic receptors 1-8. The finding that neural membranes have specific sites where KA binds quite firmly and that Glu inhibits such binding very weakly, however, raises the possibility that KA and Glu receptors may be separate and distinct (see also refs 10, 11). It is in any case known that the neurotoxic properties of KA and Glu are not identical. Thus, when injected into the amygdala, both Glu and KA destroy local neurones but only KA induces sustained limbic seizures and an apparently seizure-mediated pattern of extra-amygdaloid brain damage 12-14. Ruck et al. 15, having recently found that the folic acid derivative, methyltetrahydrofolate (MTHF), competes powerfully for KA binding sites on rat cerebellar membranes and mimics KA in depolarizing frog spinal neurones, proposed that MTHF may be an endogenous neuromodulator with both excitatory and neurotoxic properties. We have therefore injected MTHF directly into the amygdala of the adult rat and found that at a rather high dose (300 nmol), it reproduces the specific component of KA neurotoxicity that Glu fails to reproduce, namely the limbic seizure/brain damage syndrome. We have also found that folic acid itself (pteroyl-L-glutamic acid, PGA) and one of its reduced derivatives (N-5-formyltetrahydrofolate, FTHF) are substantially more powerful than MTHF in reproducing this syndrome.

Fifty-five adult Harlan rats (250-300 g) were anaesthetized with ether and Nembutal (45 mg per kg) and injected stereotaxically with KA (3 nmol), sodium MTHF (10-300 nmol), sodium PGA (25-150 nmol) or calcium FTHF (25-150 nmol) into the amygdala (Pellegrino and Cushman coordinates AP -0.4, L5, V9). Each agent was dissolved in sterile distilled water

immediately before use with NaOH added as needed to neutralize pH and improve solubility. Injections were delivered in volumes of 0.5-3.0 µl over a 5-min period through a 30-gauge needle and Hamilton microsyringe. All animals were killed by perfusion fixation 4 h after injection, as by this time the neurotoxic manifestations of KA are clearly evident in histological sections 16,17. Brains were processed for evaluation by light and

electron microscopy as described previously¹⁸.

As in earlier experiments ^{12,13,19}, KA injection (3 nmol) caused staring, mouth movements, head bobbing, eye blinking, wet dog shakes, sialorrhoea and limbic seizures which, in some animals, could be described as 'status' limbic seizures. All KA-injected animals (n = 6) had a conspicuous acute neurotoxic reaction at the local injection site, consisting of massive dilatation of neuronal dendrites, swelling of astroglia and either oedematous swelling or vacuolization and dark cell degeneration of neuronal somata. The local reaction was typically most severe in the region immediately surrounding the injection site but many amygdaloid neurones further from the injection were also damaged, as were neurones in the piriform, entorhinal and temporoparietal cortices, the hippocampus, lateral septum and certain thalamic nuclei. In some animals all these brain regions were involved but in others only a partial syndrome developed. An apparent 'mirror' focus of acute neuronal degeneration was evident in the contralateral amygdala of one animal. This disseminated pattern of damage in KA-treated animals, which several authors have attributed to a seizure mechanism 12,13,19-22, is illustrated in refs 17, 21, 22.

When MTHF was injected into the amygdala at 10, 30, 60, 100 and 300 nmol, tissue and behavioural pathology was observed only at the highest dose. Of four animals injected with this dose, three were affected; each displayed periodic KA-type seizures over a 1-2 h period and had mild brain lesions primarily involving the piriform cortex (Fig. 1a, b). Amygdaloid neurones were less consistently damaged and the tissue zone immediately surrounding the amygdala injection site was sometimes totally free from damage.

PGA and FTHF were both injected into the amygdala at 25, 50, 100 and 150 nmol (four animals at each dose of each agent) and every dose of each compound reproduced a KA-type seizure/brain damage syndrome. At 25 nmol, the seizures

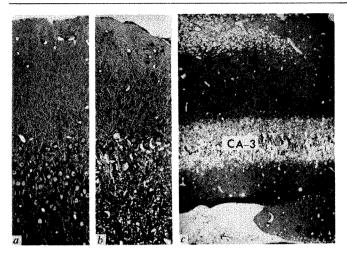

Fig. 1 a, b, The adult rat piriform cortex following injection of 60 nmol(a) or 300 nmol(b) of MTHF into the amygdala. The piriform cortex of a appears normal and this animal exhibited no behavioural pathology. The piriform cortex of b displays the typical acute cytopathological changes seen in animals following an intracerebral injection of KA (illustrated in refs 16, 18, 21); this animal had frequent KA-type seizures for 2 h (\times 106). c, The adult rat hippocampus following injection of 100 nmol PGA into the amygdala; the pattern of acute cytopathological changes is identical to that described and illustrated elsewhere²¹ in the hippocampus of KA-treated rats. Note the extreme oedematous changes in dendritic and glial structures which form a band of rarified tissue in the CA-3 pyramidal layer and the dilated distal CA-3 apical dendrites (arrows) and distal dentate granule dendrites (arrowheads) (×60).

induced by either agent were relatively mild and the brain damage largely confined to the olfactory cortex, although cytopathological changes were also sometimes detected both at the local amygdaloid injection site and in several remote brain regions. At 100 and 150 nmol, animals typically manifested severe KA-type behavioural symptoms including sustained limbic seizures, and their brains exhibited the full pattern of cytopathological changes associated with KA treatment (Fig. 1c). However, the tissue reaction at the amygdala injection site was not identical to that induced by KA in that damage to neuronal groups adjacent to the injection site was sometimes either mild or nonexistent.

When KA (2-10 nmol) is injected into the rat striatum, it destroys many local neurones²³ and, in addition, induces sustained seizures which are accompanied by the disseminated pattern of apparently seizure-mediated brain damage associated with KA injection into the amygdala 17.24. Intra-striatal injection of Glu (500-1,000 nmol) or the potent linear aspartate analogue N-methyl aspartate (40-80 nmol) also results in acute destruction of striatal neurones, but is not accompanied by either seizures or disseminated (distant) brain damage^{7,13,24}. To discover whether folates reproduce both the local and distant neurotoxic actions of KA, we injected PGA (50 and 100 nmol) into the striatum of halothane-anaesthetized rats; all animals (n = 6) manifested a full repertoire of KA-type symptoms, including frequent seizures, and all displayed the KA pattern of distant brain damage, but none sustained damage at the local striatal injection site²⁹. We tentatively conclude, therefore, that PGA and FTHF are partial KA-like neurotoxins which faithfully reproduce the distant (seizure-linked) pattern of KA-type damage while failing to reproduce the powerful local (direct) brain-damaging action of KA. The present finding of folateinduced damage to the amygdala can possibly be attributed to a seizure mechanism, as amygdala neurones are a vulnerable part of the excitatory limbic circuits within which this type of damage occurs. Additional studies are needed to clarify whether folates are totally without local neurotoxicity or merely display local neurotoxic manifestations more weakly than distant ones, and

whether separate mechanisms underlie the seizure-linked neurotoxic properties shared by KA and folates and the direct neurone-necrotizing properties shared by KA and Glu linear analogues.

It is believed that all the metabolic functions of folates are mediated by reduced tetrahydrofolate (THF) forms of PGA and that PGA itself is metabolically inactive. Because PGA was a much more active neurotoxin in our experiments than was its reduced derivative, MTHF, it seems unlikely that PGA neurotoxic activity is dependent on its conversion in vivo to MTHF. To explore the possibility that PGA activity depends on conversion to FTHF, we injected dihydrofolate (DHF) into the amygdala. As this compound is an intermediary metabolite in the PGA - FTHF pathway, it should convert in vivo to FTHF as readily as does PGA and, therefore, should be at least as active as PGA. However, we found DHF, like MTHF, to be quite weak in reproducing KA-like neurotoxicity¹⁴. Moreover, we injected amethopterin, an irreversible blocker of DHF reductase, into the amygdala 15 min before PGA injection¹⁴; although amethopterin presumably blocks conversion of PGA to any of its reduced forms, it did not decrease or prevent the expression of KA-like neurotoxicity. Thus, we suspect that the PGA molecule itself may have KA-like neurotoxic activity, and that FTHF independently has such activity.

A report²⁵ that PGA is not taken up by brain tissue slices is of interest here because the enzymatic conversion of PGA to reduced derivatives probably occurs intracellularly and cannot do so if PGA is not taken up by brain cells. Thus, injection of PGA into brain might be expected to result in its extracellular accumulation, allowing maximum opportunity for it to interact with neuromodulatory folate receptors, if any exist, on the external surfaces of central neurones. The efficient intracellular transport (and thus inactivation) of DHF and MTHF could explain their lower activity. This possibility, and the intriguing alternative that PGA and FTHF differ from other folates in having subtle structural features in common with KA, should be further investigated.

Others have shown that folates are convulsants 26,27, but it has not previously been demonstrated that they are also powerful brain damaging agents. Since folates are naturally present in the central nervous system and the seizure-related pattern of brain damage we describe here in folate-treated rats conforms closely to that frequently observed in autopsied brains of human epileptics²⁸, a possible role for folates in human epilepsy and epileptic brain damage warrants consideration.

KA, MTHF, PGA and FTHF were obtained from Sigma. This work was supported in part by grants from the USPHS, the Wills Foundation and Research Career Scientist Award MH-38894 (to J.W.O.).

Novel leukaemogenic retroviruses isolated from cell line derived from spontaneous AKR tumour

Viruses isolated from leukaemic and preleukaemic tissues of the AKR mouse differ in their ability to induce thymic lymphomas. The Gross passage A virus, which originates from the thymus of a leukaemic AKR mouse¹, and the MCF viruses, isolated from preleukaemic and leukaemic AKR tissues^{2,3}, accelerate the onset of disease on injection into newborn AKR mice3,4 whereas the endogenous ecotropic Akv virus, which is expressed in AKR mice from mid-gestation onward, is nonleukaemogenic3,5 What are the structural features of the genome that account for the leukaemogenic activity of these viruses? The observation that the gp70 envelope glycoprotein of the leukaemogenic MCF virus contain ecotropic and xenotropic regions⁷⁻⁹ raised the possibility that the structure of the gp70 gene was the major determinant of leukaemogenic activity2. However, a cloned, in vitro passaged, leukaemogenic isolate of the Gross A virus very closely resembles that of the nonleukaemogenic Akv virus in the gag-pol and gp70 coding regions of the genome¹⁰. Most of the differences in structure of the Gross A and Akv viruses are located within the 3'-terminal 1,000 nucleotides—this raises the possibility that sequences outside the gp70 gene which are proximal to the 3' end of the genome encode determinants of leukaemogenic activity. Due to the complex passage history of the Gross A virus we sought to isolate further leukaemogenic AKR viruses that had not been passaged in other animals to determine whether or not they resembled the Gross A virus. Here we report the isolation and characterization of new leukaemogenic viruses from a lymphoid cell line derived from a spontaneous AKR tumour. These isolates resemble the Gross A virus in the 3' region of the genome. Our results suggest that this region encodes determinants of leukaemogenic potency and that major changes in the envelope glycoprotein are not necessary for the leukaemogenic activity of these viruses.

The source of virus was the SL3 cell line, established from a spontaneous tumour of an AKR mouse⁵, that produces a low titre of an ecotropic, N-tropic, XC virus 5.6. To obtain clonal isolates of this virus, the cell-free supernatant of the SL3 cell line was used to infect a culture of NIH 3T3 cells. Viruses were cloned from the supernatant of the infected culture by two rounds of end point dilution. For each round of cloning, less than one in five wells contained virus at the end point. Two viruses, SL3-1 and SL3-2, were obtained in one such experiment; the SL3-3 virus was obtained in a separate but similar experiment.

The biological properties of the cloned and uncloned SL3 were determined (Table 1). All viruses obtained from the SL3 cell line are ecotropic and N-tropic. The SL3-1 and SL3-3

viruses are positive in the XC fusion test, whereas the SL3-2 virus is not. The ratio of infectious virus to reverse transcriptase activity is much higher for virus grown in NIH 3T3 cells than for virus produced by the SL3 cell line.

The cloned SL3 isolates retain potent leukaemogenic activity (see Table 1): injection of these viruses into newborn AKR mice results in 100% incidence of thymic lymphoma with an average latent period of ~80 days. Mock-inoculated controls do not develop disease before 220 days. The pathology of the accelerated disease is indistinguishable from the spontaneous AKR or Gross passage A virus-induced thymic lymphoma. The cloned SL3-2 and SL3-3 isolates also induce rapid leukaemia in C3H_f/Bi mice (100% incidence, mean latent period of 100 days). Normally, these animals have a negligible incidence of thymic leukaemia. Our preliminary results indicate that the SL3-3 isolate also induces rapid thymic leukaemia in NSF-N mice—these animals show a pathology typical of Gross passage A-induced disease.

The structure of the SL3 viral RNAs was analysed using high resolution methods for analysis of RNase T₁-resistant oligonucleotides^{11,12}. Fingerprints of 70S RNAs of virus produced by the uncloned SL3 virus grown on NIH 3T3 cells and the cloned isolates are shown in Fig. 1, together with schematic interpretations. The fingerprint of the virus produced by the SL3 cell line itself is indistinguishable from that of the uncloned SL3 virus grown on NIH 3T3 cells. The schematic interpretations are based on co-electrophoresis of labelled oligonucleotides with those of the Akv virus, and on complete or partial sequence analysis of each numbered oligonucleotide. The fingerprints of the cloned virus indicate that they are biochemically pure and the molar yield of the unique oligonucleotides is close to unity in each isolate. The fingerprints of the cloned viruses do not change on subsequent cloning or passage of these isolates. The order of the unique oligonucleotides along the genome was determined (see Table 2). The sequence of the oligonucleotides of the SL3 viruses that are not present in the fingerprint of the Akv virus were also determined (see Table 3).

The map of Table 2 shows that oligonucleotides 208B and 36B are located near the 3' terminus of the SL3 viruses. It is striking that identical oligonucleotides are also found in the same relative positions in the leukaemogenic Gross A/NIH virus¹⁰. The sequence of oligonucleotides 208B and 36B differ from sequences in the Akv virus by one or two base changes; except for these two oligonucleotides and a few in the gag-pol region of the genome, the SL3-1 and SL3-3 viruses are identical to the Akv virus within the limits of resolution of the fingerprinting method, yet the SL3 viruses are potent leukaemogenic agents. Evidently, slight changes in the genome structure can affect the leukaemogenic activity of AKR viruses.

The SL3-2 virus differs from those of SL3-1 and SL3-3 cell lines in the region that encodes the gp70 protein. Most of this region is substituted with a heterologous sequence. One explanation for the isolation of two different viruses from the same cell line is that the SL3 cell produces a mixture of two viruses that have a large part of the genome that is identical but differ in the gp70 gene. The observation that, in the uncloned viruses, the oligonucleotides derived from the gp70 region of the genome are present in half the molar yield of the other oligonucleotides in the genome supports this notion (data not shown)

We have also studied viruses produced by eight other lymphoid tumour cell lines of AKR origin. Four of these produce mixtures of virus identical to those produced by the SL3 cell line and which also have the changes in the gag-pol and env regions noted here. Comparison of these viruses will be the subject of a separate communication.

Some of the gp70 oligonucleotides of the SL3-2 virus are identical to sequences found in fingerprints of a xenotropic virus chemically induced from AKR fibroblasts¹³ (see Table 3). As is the case for MCF viruses isolated from AKR tissues, substitution of xenotropic virus-related sequences within gp70 correlates with the XC⁻ phenotype of the SL3-2 virus. Unlike the

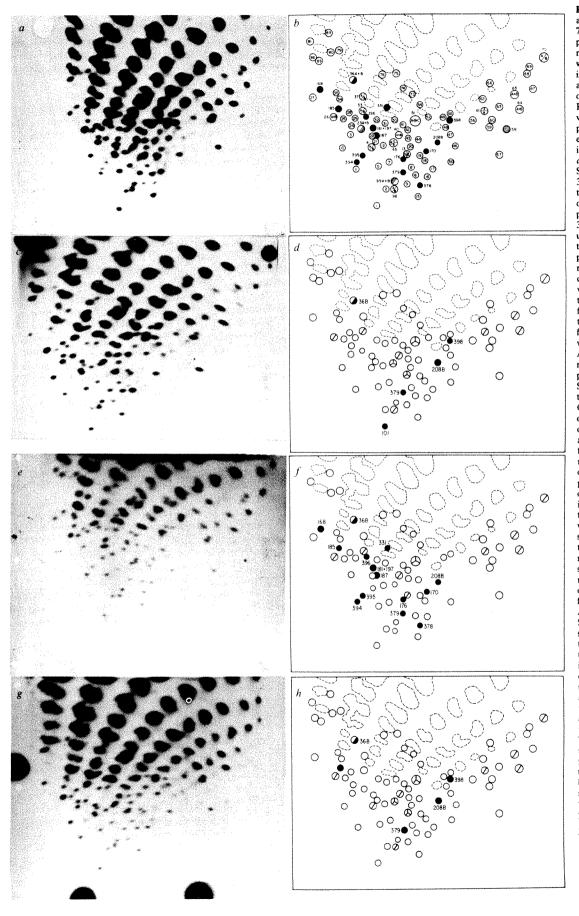

Fig. 1 RNase T_1 fingerprint analysis of SL3 viruses. Viral 70S and 35S RNAs were prepared from cell-free supernatants as described else-where 11,12. The schematic The schematic interpretations are based on (1) analysis of mixtures of labelled oligonucleotides of each viral RNA with those of the Akv virus and; (2) complete or partial sequence analysis of each numbered oligonucleotide in the fingerprints of each virus. a, b, 70S RNA of the uncloned SL3 virus propagated on NIH 3T3 cells. The fingerprints of the virus produced by a subline of the SL3 cell line, and virus produced by two other NIH 3T3 cultures infected with the uncloned SL3 virus were indistinguishable from this fingerprint, shown in a. Open circles represent oligonucleotides common to the Akv and SL3 viruses. The Akv virus used for this comparison was derived from the same mouse colony that gave rise to the SL3 cell line from (from Esther Hays, University of California, Los Angeles). Solid circles oligonucleotides represent present in the fingerprint of the SL3 virus that are not present in the fingerprint of the Akv virus. Cross-hatched circles represent oligonucleotides characteristic of the Akv genome that are absent altogether from the fingerprint of the SL3 virus. The numbering of the Akv oligonucleotides is as described previously12. The numbering of oligonucleotides 208B and 36B is the same as that assigned to the Gross A oligonucleotides which have identical sequence 10. c, d, 70S RNA of the SL3-1 isolate. Open circles oligonucleotides represent shared with the Akv virus; solid numbered circles represent oligonucleotides that are not found in the fingerprint of the Akv virus. e, f, 35S RNA of the SL3-2 isolate; symbols are the same as for d. g, h, 70S RNA of the SL3-3 isolate; symbols are the same as for d. Although not indicated in the schematic drawings, the same Akvspecific oligonucleotides that are missing from the fingerprints of uncloned SL3 virus are also missing from the finger-prints of the cloned derivatives. The molar yields of each of the unique oligonucleotides of each fingerprint were determined in two independent experiments by counting gel fragments corresponding to the position of the oligonucleotides. The molar yield of each of the unique oligonucleotides was the same, within experimental error, in the fingerprints of the cloned viruses. For the uncloned SL3 virus, the molar yield of the oligonucleotides in the gp70 region of genome (see Table 2) was half that of the other oligonucleotides.

AKR-MCF viruses, the gp70 substitution in SL3-2 apparently does not result in an extended host range. More important, the gp70 substitution in SL3-2 is not essential for the leukaemogenic potential of the virus, as the SL3-1 and SL3-3 viruses which lack the substitution are also potent leukaemogenic agents.

What functions relevant to leukaemogenic activity may be

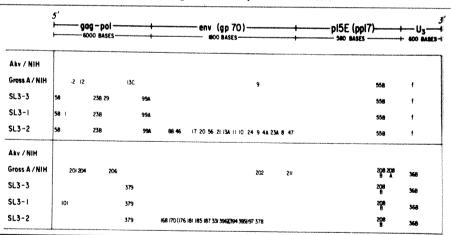

altered in the SL3 viruses? All the SL3 isolates differ slightly from the Akv virus in the gag-pol region of the genome. It is possible to argue that these differences correlate with oncogenic potential. However, the Gross A/NIH virus also contains changes in this region of the genome, but these sequences are not the same as those present in the SL3 viruses. Therefore, we consider it more likely that the variant 3' region of the genome

The biological properties of the viruses were determined using standard methods. The viruses used were Akv and Gross A/NIH described elsewhere ¹⁰⁻¹²; AKR MCF-247; a xenotropic virus, AKR-6, derived from tissues of an AKR mouse propagated on dog 8155 cells, and the SL3 viruses described in the text. The same preparation of each virus was used for all tests. The ability of the viruses to grow on mouse NIH/3T3 and BALB/c cells, mink CCL64 cells, dog 8155 cells, and cat FLF₃ cells was determined by assay of reverse transcriptase activity in cell-free supernatants. The reverse transcriptase activity produced per cell was determined by dividing the c.p.m. incorporated by the virus in 1 ml of culture fluid in a standard reverse transcriptase assay by the number of cells per ml (in the case of suspension cultures) or the number of cells per ml of supernatant (for adherent cells). The end point titre (in Infectious Units, IU) was determined in NIH3T3 cells. The S+L- and XC fusion assays are those described elsewhere ^{22,23}. PFU, plaque-forming units. The leukaemogenic activity of each virus was determined by inoculation of 0.1 ml of cell-free supernatant intraperitoneally into 2-4-day-old AKR and C3H_t/Bi mice. Mockinjected littermates served as controls in all cases. Experimentally induced acceleration of disease in AKR mice was clearly a separate event from that of spontaneous disease in control littermates. All eight animals injected with the uncloned SL3 virus grown on NIH3T3 cells. (SL3/NIH) developed leukaemia in 69-104 days with an average onset of 87 days, whereas seven control littermates did not develop disease before 220 days. All five animals injected with the SL3-1 virus developed disease at 120-14 h.days, average 124 days post-inoculation, whereas three uninoculated littermates did not develop disease before 220 days. All eight animals injected with the SL3-3 virus developed disease between 61 and 82 days whereas sight control littermates remained disease-free at 230 days post-inoculation. Induction

Table 2 Oligonucleotide maps of the SL3 viruses

The order of the large T_1 oligonucleotides of the genome of the SL3-2 virus was determined as described elsewhere 10 . The map order of the Akv and Gross A/NIH viruses are those described elsewhere 10 . The map order of the oligonucleotides of the SL3-1 and SL3-3 viruses are inferred by comparison with the maps of the Akv, Gross A/NIH and SL3-2 viruses. The upper half represents oligonucleotides, present in Akv, which are missing from these viruses, the lower half represents the positions of oligonucleotides which are not present in Akv. For the Akv genome, there are a total of 34 oligonucleotides within the gag-pol region, 16 within gp70, 9 within p15E, and 6 within U_3 . The assignment of oligonucleotides 88 and 46 to the *env* region of Akv, Gross A, SL3-1, and SL3-3 is further supported by alignment of these sequences with the protein sequence of the *env* gp70 proteins of the Moloney and Rauscher murine leukaemia viruses 24 . This alignment is indicated below

An asterisk indicates positions in which the oligonucleotide sequence differs from that predicted by the amino acid sequence. The alignment of oligonucleotides with p15E-R and U_3 is further supported by DNA sequences of the Moloney leukaemia 15 and Akv viruses (W. Herr, personal communication and J. Lenz, R. Crowther, A. Straceski and W. Haseltine, unpublished data). In addition to those shown, the Gross A/NIH virus possesses oligonucleotides numbered 205, 207, 213 and 215, which, by fingerprint analysis, map within the extreme 3'-terminal regions. Their precise locations relative to other oligonucleotides within p15E and U_3 are unknown.

The complete sequence of the non-Akv oligonucleotides present in the fingerprints of the SL3 viruses was determined as described elsewhere 10-12. Several of these sequences are related by one or two base changes to oligonucleotides present in the fingerprints of the Akv and Gross A/NIH RNAs. Such sequence variations are indicated for oligonucleotides 36B, 208B, 197, 101 and 378 of the SL3 viruses which are related to oligonucleotides 7, 55B, 197, 1 and 9 of the Akv virus, respectively. The sequences of oligonucleotides 208B and 36B of the SL3 viruses are identical to oligonucleotides of the same number in the Gross A/NIH virus. The sequence of the SL3-specific oligonucleotides for which no Akv analogues were found are also listed in the lower half of the table. The sequence of two of the oligonucleotides derived from the gp70 gene of the SL3-2 virus, numbers 170 and 176, are identical to oligonucleotide sequences present in the fingerprint of xenotropic virus induced from AKR fibroblasts (unpublished observations).

U C G

affects the leukaemogenic activity of the viruses, as identical changes in this region of the genome are observed in the genomes of the leukaemogenic Gross A and SL3 viruses. Furthermore, the same variant 3' region, characterized by oligonucleotides 208B and 36B, is also present in the RNA of virus produced by four other independently isolated lymphoma cell lines which were derived from spontaneous tumours of AKR mice that produce leukaemogenic viruses (refs 5, 6, 14, and unpublished observations).

UAUUA

Changes in the 3' region could affect several viral functions. Sequence analysis of recombinant DNA fragments of the Moloney murine leukaemia virus (Mo-MuLV) provirus reveals a continuous coding sequence that runs from the amino terminus of the gp70 protein to the origin of plus strand synthesis at the 5' end of the U³ region¹⁵. The open reading frame extends past the end of the p15E gene. An open reading frame in this region of the Akv genome is also indicated by the preliminary sequence of this region (W. Herr, personal communication, and J. Lenz, R. Crowther, A. Straceski and W. Haseltine, unpublished observations). Comparison of the sequence of oligonucleotide 208B with that of the Akv sequence implies that the protein coded for by the SL3 virus would differ from that corresponding to the Aky protein by a change from an Arg-Leu sequence to His-Met sequence near the carboxyl region of the p15E region as indicated below.

	G	ross A/N	IIH and	SL3 sec	uence	
5'	Cys GT	Ile ATT	Leu CTC	Asn AAT	His CAC	Met ATG
5'	Cys GT	Ile ATT		Asn AAT		
		A	kv seat	ience		

Much of the protein sequence coded for by the p15E region of the genome would not be affected, because the other oligonucleotides derived from this region are identical in the Akv, SL3 and Gross A/NIH viruses. A possible explanation for the leukaemogenic activity of these viruses is that the 3'-terminal region of the virus encodes a protein that is active in the transformation process and that this protein has different structures in the leukaemogenic and nonleukaemogenic viruses.

Oligonücleotide 36B may also serve as a marker for leukaemogenic activity. This oligonucleotide is located in the U₃ portion of the genome and is related to an oligonucleotide in the Akv virus by a single base change. The U3 region of the virus codes for functions that are important for the replication cycle, including initiation of the plus strand of DNA synthesis, initiation of RNA transcription, processing of RNA transcription and possibly integration 16-18. Changes in the structure of the region of the genome that controls this process could alter the physiological effects of virus infection on cell growth and regulation. Recent studies of the recombinants between the avian retroviruses RAV-0 and RAV-2 also suggest that leukaemogenic activity might be associated with structural determinants at the extreme 3' terminus of the viral genome 19,2

We thank Dr E. F. Hays for providing the SL3 cell line and for helpful discussion and Drs W. Herr, C. Van Beveren and I. Verma for providing us with unpublished DNA sequences of the Aky virus. F. S. P. was a fellow of the Leukaemia Society of America. W. H. is a recipient of an American Cancer Society Faculty Research Award. This work was supported by NCI awards CA25118 and CP7-1057.

Identification of E. coli uvrC protein

George H. Yoakum & Lawrence Grossman

Department of Biochemistry, School of Hygiene and Public Health, The Johns Hopkins University, 615 North Wolfe Street, Baltimore, Maryland 21205, USA

The excision of pyrimidine dimers from DNA is one of the major mechanisms of repair involving an initial endonucleolytic step followed by excision, resynthesis and ligation¹. The enzymatic mechanism for endonucleolytic cleavage of UV light-damaged DNA by the Micrococcus luteus2 and Escherichia coli bacteriophage T4 (ref. 3) dimer-specific endonucleases involves two steps: cleavage of the N-glycosylic bond of the 5'-pyrimidine moiety of the pyrimidine dimer, followed by cleavage of the phosphodiester bond 3' to the apyrimidinic site produced by the first step. Although E. coli requires functional uvrA, uvrB and uvrC genes to repair UV light-damaged DNA4, and enzymatic cleavage of damaged DNA requires the concerted action of at least three proteins⁵⁻⁸, the mechanism of catalysis by which the uvr-endonucleolytic system cleaves UV light-damaged DNA is unclear. We have constructed hybrid multicopy plasmids containing the uvr genes of E. colis to study the expression of amplified uvr genes. We have physically mapped uvrC on plasmid pGHY4211 (previously referred to as pGY4211 (ref. 9)) by interruption with the $\gamma\delta$ sequence of F⁺ as described by Guyer¹⁰, and determined the minimum size for the uvrC gene to be 1.45 kilobase pairs. SDS-gel electrophoresis of radioisotopically labelled plasmid proteins indicates that the uvrC⁺ gene product is a polypeptide of molecular weight (MW) 68,000. We estimate that wild-type E. coli may have as few as 10 copies of uvrC polypeptide per cell.

We have previously described a set of plasmids, consisting of pBR322 and a 3.4-kilobase pair PstI fragment of E. coli K12 DNA, which complements the uvrC34 mutation in either orientation relative to pBR322 (pGHY4211, pGHY3233)9. To study the role of uvrC in the uvr repair system of E. coli we have physically mapped the uvrC gene, and identified the uvrC protein by SDS gel electrophoresis of plasmid proteins labelled by the maxi-cell¹¹ method.

Inactivation mapping of cloned genes has proved useful in determining the physical size, direction of transcription and identification of gene products¹²⁻¹⁵. The $\gamma\delta$ -insertion sequence of F was used to identify the uvrA and uvrB gene products in a similar manner^{16,17}. This insertion sequence integrates into DNA by a recA-independent mechanism¹⁰, and DNA sequencing indicates that termination signals occur in five of the six possible reading frames near the ends of the $\gamma\delta$ sequence (M. Guyer, personal communication). Thus, insertion of the $\gamma\delta$ sequence into a structural gene terminates translation in almost all cases. The F⁺ recA56 streptomycin-sensitive (Str^s) strain (MG1063) used here to isolate $\gamma\delta$ insertions in plasmid pGHY4211 was provided by M. Guyer¹⁰, and was transformed¹⁸ with pGHY4211. Transconjugants of pGHY4211 containing $\gamma\delta$ insertions were isolated by mating tetracyclineresistant (Tetr) MG1063 carrying pGHY4211 with an F recA56 uvrC34 rpsL strain (SR57, Kendric Smith). To select recipient cells carrying pGHY4211 with $\gamma\delta$ insertions, cultures were plated on Luria agar containing 10 µg ml⁻¹ tetracycline and 50 µg ml⁻¹ streptomycin, and colonies were tested for Tet and Str (ref. 10). About 200 Tet Str colonies were tested for UV light sensitivity as described elsewhere9. Several colonies carrying plasmids unable to complement the uvrC34 mutation of SR57 (recA56 uvrC34) were selected for further study, and small amounts of plasmid DNA isolated by a rapid isolation procedure¹⁹. The recA56 uvrC34 double mutant (SR57) was transformed with the plasmid DNAs isolated above, screened

for Tet', Str' and UV light sensitivity, then stored at -20 °C in glycerol cultures for later use in protein labelling experiments.

The site of integration was determined for 10 $y\delta$ insertions in pGHY4211 which inactivate the $uvrC^+$ function of this plasmid, by measuring the size of restriction fragments after digestion with EcoRI or BamHI. pGHY4211 contains only one EcoRI and one BamHI site in the pBR322 portion20 of this 7.76kilobase pair plasmid9. Therefore, the EcoRI site located at 0.9 kilobase pair from the y end and the BamHI site at 0.4 kilobase pair from the δ end of the insertion sequence 10 allow an unequivocal location of the site of $\gamma\delta$ insertion and its relative orientation, by determining the size of the EcoRI and BamHI restriction fragments on agarose gels. Mapping data yielded the locations of $y\delta$ insertions (shown in Fig. 1), indicating that the minimum size for the uvrC gene transcription unit is 1.45 kilobase pairs. This is enough genetic information to encode an average polypeptide of MW 56,000.

SDS-polyacrylamide gel electrophoresis²¹ of ³⁵S-Metlabelled proteins encoded by γδ-inactivated pGHY4211 plasmids, reveals that a 68,000-MW polypeptide is missing in each case (Fig. 2b). This 68,000-MW polypeptide is present among the plasmid-encoded products of pGHY4211 and pGHY3233 (Fig. 2a, b) which contain the uvrC+ 3.4-kilobase pair Pst1 fragment in both orientations relative to pBR322. As the uvrC gene transcription unit in pGHY4211 maps between 0.85 and 2.3 kilobase pairs (Fig. 1), and a 68,000-MW polypeptide is missing from the plasmid-encoded products of each γδinactivated plasmid, these data indicate that the 68,000-MW polypeptide is encoded by uvrC. However, these data do not preclude the possible disappearance of a low-molecular weight polypeptide, fortuitously similar to a low-molecular weight polypeptide among $\gamma\delta$ plasmid-encoded background bands in Fig. 2. Although identification of the uvrC gene product must also be established by conventional protein purification methods, the 68,000 molecular weight observed here is in the same range suggested for uvrC from complementation activity in E. coli extracts7.

Additional evidence that the 68,000-MW polypeptide is encoded by the uvrC gene was obtained by in vitro mutagenesis of pGHY3233. Mutations in the uvrC⁺ gene of pGY3233 were isolated by irradiation of plasmid DNA with various doses of UV light and transformation 18 of irradiated plasmid DNA into rec⁺ uvrC34 AB1884 (ref. 4). About 800 Tet^r transformants were tested for Tet and UV light sensitivity as previously described9. From these, two colonies were found which carried Tet' plasmids that were unable to complement the uvrC34 mutation. After isolation of a small amount of plasmid DNA, SR57 recA56 uvrC34 was transformed with pGHY7077 and pGHY7064 and cultures tested for Tet and UV light sensitivity and placed in storage as described above. pGHY7077 and

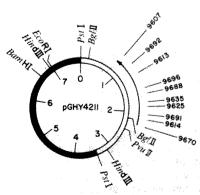

Fig. 1 $\gamma \delta$ insertion map of the *uvrC* gene in plasmid pGHY4211 including the minimum physical size of the uvrC gene transcription unit, and the most probable direction of transcription. The site of $\gamma\delta$ integration in pGHY4211 was determined by restriction mapping as described in the text. The most distant sites of integration which inactivate the uvrC⁺ function of pGHY4211 are at 0.85 kilobase pair (9607) and 2.3 kilobase pair (9670), indicating a minimum size of 1.45 kilobase pair for uvrC.

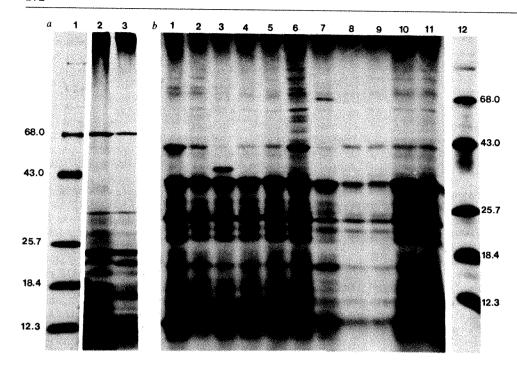

Fig. 2 The 35S-Met-labelled protein products of various plasmids were visualized by fluorography of maxi-cell extracts resolved on 10-20% polyacrylamide gradient2% SDS gels by electrophoresis, as described in the text. The first lane in a contains 14 C-labelled protein standards obtained from Bethesda Research Laboratories. Lane 2 contains ³⁵S-Met-proteins from *uvrC*⁺ pGHY3233 (ref. 9); lane 3, ³⁵S-Met-labelled proteins from pGHY4211. b, Fluorography of a similar polyacrylamide gel used to resolve the 35S-Met-labelled proteins encoded by the plasmid indicated for each lane. The electrophoretic mobility of protein 14Clabelled standards is indicated in the margin. Lane 1, $\gamma\delta$ -9607; lane 2, $\gamma\delta$ -9866; 3, γδ-9613; 4, γδ-9614; 5, γδ-9625; 6, γδ-9670; 7, pGHY4211 (uvrC⁺); 8, pGHY7064 (uvrC⁻ mutation); 9, pGHY7077 (uvrC mutation); 10, γδ-9691; 11, $\gamma \delta$ -9696. The appearance of a number of bands in lane 6 ($\gamma\delta$ -9670) could have resulted from an increase in background due to a low level of contamination for this extract.

pGHY7064 plasmid DNAs were digested with PstI and Hin dIII and compared with pGHY3233 by agarose gel electrophoresis (data not shown). Both pGHY7077 and pGHY7064 contain the 3.4-kilobase pair PstI fragment in the same orientation as their $uvrC^+$ counterpart, pGHY3233 (ref. 9). Radioisotopic labelling of plasmid-encoded proteins from $uvrC^-$ pGHY7077 and pGHY7064 derived by $in\ vitro\ UV$ light mutagenesis lack a 68,000-MW polypeptide (Fig. 2b). This confirms the conclusion drawn from the $\gamma\delta$ -inactivation experiment that the 68,000-MW polypeptide is encoded by the uvrC gene.

The most probable orientation of uvrC transcription was deduced from the polypeptide products and map position of $\gamma \delta$ -9613—this maps at 1.275 kilobase pairs (Fig. 1), and produces a unique polypeptide of MW 35,000 (Fig. 2b, lane 3). The appearance of this polypeptide among the 35S-Met-labelled products of a plasmid that is unable to produce the 68,000-MW polypeptide and inactivated for uvrC complementation, suggests that the 35,000-MW polypeptide is a partial product of uvrC. Because the 1-kilobase pair distance between 9613 and 9670 is adequate to encode an average polypeptide of MW~ 38,300, and the 420 base pairs from 9613 to 9607 could only encode ~16,200 MW, the position of 9613 and the 35,000-MW polypeptide are most consistent with a starting point for the uvrC gene close to 9670, with transcription proceeding towards 9607 (Fig. 1). In addition, we found that $\gamma\delta$ -9692 produces a similar truncated polypeptide (data not shown) to that produced by $\gamma \delta$ -9613, supporting the orientation of transcription deduced from the distribution of $\gamma\delta$ inserts which inactivate the uvrCgene and the 35,000-MW truncated product from $\gamma \delta$ -9613.

To estimate the approximate number of uvrC polypeptide chains synthesized in wild-type $E.\ coli$, we compared the densitometric intensity of the uvrC and ssb bands from the labelled protein products of a $uvrC^+\ ssb^+\ uvrA^+$ composite plasmid $(pGHY4610)^9$. After labelling maxi-cell extracts of pGHY4610 ($uvrA^+\ ssb^+\ uvrC^+$) with ^{14}C -amino acid mixtures consisting of 20 amino acids present in similar specific activity, the labelled products were visualized by SDS-polyacrylamide gel electrophoresis and fluorography as described above. Autoradiographic films were exposed for various lengths of time and densitometric scans made. A comparison of the ssb^+ band, present in 1,200 polypeptide chains per $E.\ coli\ cell^{22}$, with the $uvrC^+$ band, indicates that uvrC may be present in as few as 10 copies per cell (Fig. 3).

The *uvrC*⁺ protein of *E. coli* is identified as a 68,000-MW protein on SDS-polyacrylamide gels. This protein is required for

ATP-dependent incision of DNA containing pyrimidine dimers⁷ and psoralen cross-links²³, as well as incision due to the presence of several other types of DNA damage in *E. coli*. Seeberg^{7.8} reported that $uvrB^+/C^+$ -complementation activity can be detected from Sephadex gel columns corresponding to \sim 70,000 MW—this agrees well with our observation that uvrC encodes a 68,000-MW protein on SDS gels. Previous attempts

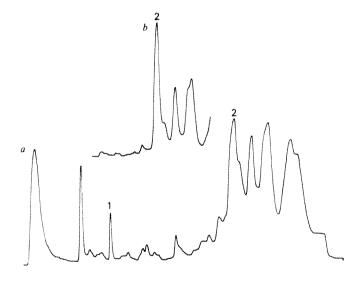

Fig. 3 Densitometric comparison of 14 C-labelled uvrC and ssb protein bands after SDS-polyacrylamide gel electrophoresis of extracts from $uvrC^+$ ssb^+ $uvrA^+$ pGHY4610 (ref. 9). The tracing shown in a includes the entire gel; the film was exposed for 8 days. The uvrC protein band is indicated by 1, and ssb by 2. As the ssb band is overexposed on this film (a), a second film was exposed to this gel for 1.6 days; the result is shown in b. The uvrC peak (1) in a was compared with the ssb peak (2) in b for this estimate. This comparison was based on the area of each peak, the relative size of uvrC and ssb polypeptides, and the relative time of exposure for each film. As ssb is present in 1,200 copies per cell²² and its molecular weight is 18,500 (ref. 22), these data provide an estimate of \sim 10 uvrC polypeptide chains per log-phase E. coli cell, assuming that there is a similar ratio of expression in vivo and in maxi-cells for uvrC and ssb.

to determine the mechanism of dimer-specific endonucleases in E. coli have been hampered by the twofold problem of identification of the elements of a 3-gene system (that is, uvrA, uvrB and uvrC) and the presence of very low amounts of UV dimer-specific activity. Our identification of the uvrC protein as a product from a multicopy plasmid provides a means to purify uvrC protein in sufficient quantities to allow its characterization as a component of the 3-gene product system required for incision of UV light-irradiated DNA.

We thank Dr Roger L. McMacken for comments during the study and preparation of the manuscript. This work was supported by American Cancer Society grant NP8K, and by National Institutes of General Medical Sciences grant 2 R01 GM22846 to L.G.

Positively activated transcription of λ integrase gene initiates with UTP in vivo

U. Schmeissner*, D. Court*, K. McKenney† & M. Rosenberg†

*Laboratory of Molecular Biology and †Laboratory of Biochemistry, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

Bacteriophage & requires two viral gene products for lysogenic development-repressor (cI) and integrase (int). Although the genes for these two proteins are located in distinct operons. separated by 9,000 base pairs (bp) of the phage genome, their expression is coordinated by the positive regulation of transcription mediated by another phage-encoded protein, cII (see ref. 1 for review). We have already identified the promoter signal for the establishment of repressor synthesis (PE) and demonstrated that cII protein is required for the initiation of transcription at this site. Here we determine the precise in vivo start site for int mRNA and demonstrate that transcription from this site is also cII-dependent. This start site defines the int promoter P₁. Atypically, transcription from P₁ initiates with UTP. Comparison of the nucleotide sequences of the P_i and P_E promoters reveals a striking homology in identical positions between 26 and 39 bp upstream of their respective start sites.

Our objective was to describe the mechanism of transcription in the xis-int region of phage λ and to study the effect thereon of cII expression (see ref. 2). A 417-bp \(\lambda \) DNA fragment, extending from 280 bp upstream of the xis coding sequence to include 150 bp of the xis gene as far as the structural int gene³ purified and inserted into the plasmid pBR322 (Fig. 1). The DNA of the recombinant plasmid (pUS3) was used to purify RNA made from this region during phage infection by a singlestep hybridization procedure (see Fig. 2 legend and ref. 2). RNA was labelled by exposing cells to ³²P-orthophosphate between 10 and 11.5 min after infection—an interval chosen to minimize degradation of the mRNA. This specific RNA (Fig. 2) was characterized by T1 ribonuclease digestion and separation of the resulting oligonucleotides by a two-dimensional fingerprinting technique⁶. The T1 fingerprints were prepared from RNA isolated from cells infected with either $\lambda c \text{II}^-$ (Fig. 2a) or $\lambda c \text{II}^+$ (Fig. 2b). The major (numbered) oligonucleotides were further digested with pancreatic ribonuclease and the products separated by one-dimensional electrophoresis on DEAE paper at pH 3.5 (ref. 6). The results of these analyses allowed us to determine the composition of each T1 oligonucleotide and to position it unambiguously within the known DNA sequence3 of the 417-bp fragment (Fig. 3).

RNA from $\lambda c II^-$ infection yielded equimolar amounts of oligonucleotides spanning the entire fragment (Fig. 3, oligonucleotides 1-9 and 11-17), indicating uniform transcription throughout the region; transcription probably originates at the upstream promoter P₁ (Fig. 1). In contrast, for RNA from λc II infection, the intensity of oligonucleotides 11-17 was increased some eightfold, whereas the intensity of oligonucleotides 1-9

Fig. 1 Partial genetic map of phage λ. Indicated are the two cII-dependent promoters P_E (responsible for the establishment of repressor synthesis) and P_I (responsible for the production of integrase). Other λ promoters (P_L, P_R, P_O, P_M) also shown, as is the direction of transcription from these sites (wavy arrows). The 417-bp DNA restriction fragment shown below the map was inserted into the plasmid pBR322 by blunt-end ligation. The resultant plasmid (pUS3) was used in the hybridization experiments as described in the text.

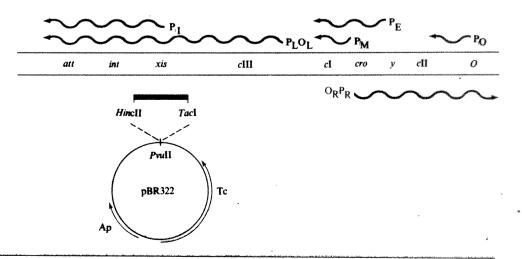

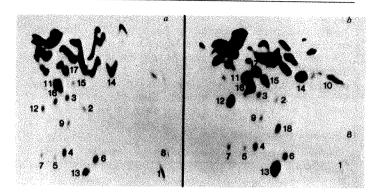

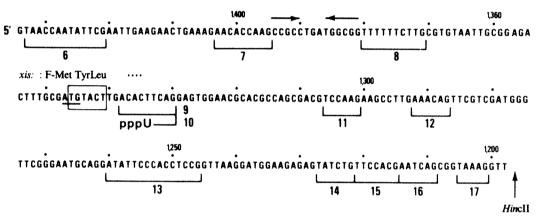

Fig. 2 Two-dimensional fingerprints of ribonuclease TI oligonucleotides derived from RNA transcribed in vivo from the xis-int region of phage λ . Fingerprints were prepared from RNA isolated after infection of Escherichia coli K12 SA500 (his, rpsL) with $\lambda c I_{14} c II_{28} c III_{611}$ (a) or $\lambda c I_{14}$ (b)¹¹. Total RNA was extracted as described by Court et al.¹² and hybridized to plasmid pUS3 DNA bound to filters. Hybridizations were carried out at 67 °C for 6 h as described elsewhere². RNA purified by this single-step hybridization procedure was digested with ribonuclease T1 and the products separated by standard fingerprinting techniques. Horizontal dimension, electrophoresis on Cellogel strips at pH 3.5. Vertical dimension, homochromatography on thin-layer plates of DEAE-cellulose using Homomix C. The numbered oligonucleotides in each fingerprint were further analysed by digestion with pancreatic ribonuclease⁶. The results of these analyses are summarized in Fig. 3. In addition, oligonucleotide no. 10 was treated with nuclease P.

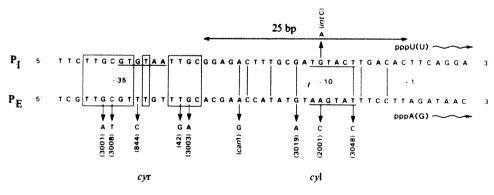

and the resulting mononucleoside-5' phosphates fractionated by two-dimensional chromatography². The results (not shown) indicate that this oligonucleotide contains the triphosphate, identified as pppU. Oligonucleotides 1 to 5 are not shown in Fig. 3; these correlate with the DNA sequence 5' to that shown in Fig. 3 (that is, beyond residue 1,434). Their sequences are: 1, AU₃AU₄AUCUG; 2, AUUA₃UG; 3, CACUUCCG; 4, CCAUUCAACAG; 5, AACAUCAACG. Oligonucleotide no. 18 has the sequence ACUUA₃UCG and derives from the region immediately 3' to the DNA fragment used for hybridization. The presence of this oligonucleotide probably results from the mild ribonuclease trimming conditions used to preserve the 5' end of the cII-dependent transcript during the isolation of the RNA-DNA hybrids.

Fig. 3 Nucleotide sequence of the P_I promoter region³⁻⁵. Only the coding strand of the DNA is shown. The orientation of the sequence is inverted relative to the position of λ genes indicated in Fig. 1. The numbering of the nucleotide positions starts in the centre of the λ attachment site⁴. Numbered brackets designate the responding oligonucleotides in the RNA fingerprints of Fig. 2. The 5' end of the RNA is indicated by pppU, and the -10

region of the promoter is boxed. Note that the transcriptional start point of the *int* mRNA lies within the *xis* coding region. This is consistent with the finding that the expression of xis is not controlled by c II (ref. 13). The arrows define a region of dyad symmetry, which is followed by the sequence T_6C . Such a structure is common to sites signalling termination of transcription 14 . However, the relative molar yields of oligonucleotides 7, 8 and 9 indicate that the transcription does not terminate at this site during our analyses.

Fig. 4 Comparison of the nucleotide sequence of the P₁ and P_E promoters. Only the coding strands of the DNA are shown. The sequences are aligned with respect to the cII-dependent transcriptional start sites used in vivo. The nucleotides in the -10 region of both promoters and in the -35 region of the P₁ promoter, which show some homology with the conserved sequences found in other promoters for E. coli RNA polymerase¹⁴, are underlined. The boxed regions indicate 11 of 14 bp which are identical in both promoters. The various

cyr and cyl mutations which eliminate P_E promoter function are indicated, as in the can mutation which alters the second codon of the cII structural gene but has no effect on P_E promoter function. Also shown is the int mutation which occurs in the -10 region of the P_I promoter and results in cII-independent, constitutive expression of gene int.

was similar to that from $\lambda c II^-$ infection. In addition, a new oligonucleotide (no. 10, Figs 2, 3) was identified as the pentamer pppUUCAG. These results indicate that in the presence of c II, a new transcript starts at a site located 183 bp before the translation initiation codon of *int* and 13 bp downstream of the AUG initiation codon of *xis* (at position 1,334 in Fig. 3 as numbered from the centre of the core of the *att* site⁴). This c II-dependent RNA accounts for over 80% of the *int* gene transcripts made during the pulse-labelling interval.

Identification of the 5' end of this RNA defines the c II-activated P_1 promoter.

Note that the P_I transcript initiates with UTP. This is the first in vivo demonstration of the use of UTP by RNA polymerase to initiate transcription. Recently, it has been shown that purified cII protein causes RNA polymerase to initiate transcription in vitro at the same UTP start. This demonstrates that the positive activation observed at P_I in vitro accurately represents the in vivo situation.

Hoess et al.4 and Abraham et al.5 have determined the base change associated with the mutation intC (Fig. 4) that allows cII-independent, constitutive expression of int. More recent work8 indicates that the intC mutation also allows RNA polymerase to initiate transcription in vitro from the same UTP start as demonstrated here. Our finding confirms the earliest suggestion that intC is a promoter-up mutation affecting the -10 region of the P_I signal^{4,5,8}.

We have compared the nucleotide sequences of P_E and P_I by aligning them with respect to their in vivo start sites. Homology in 11 of 14 bp is observed at identical positions in the -35 region of both promoters. This finding further supports the proposal^{2,8,9} that this region of the promoter is involved in the positive activation mechanism, perhaps as a site of interaction with protein cII.

We thank J. Abraham and H. Echols for communicating results before publication, R. Steinberg for photographic work and P. Donoghue for typing the manuscript.

Heterogeneous host DNA attached to the left end of mature bacteriophage Mu DNA

Marie George & Ahmad I. Bukhari

Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA

Bacteriophage Mu, a highly efficient transposon during its lytic cycle in Escherichia coli, is always associated with the host DNA1. In mature Mu particles, both ends of Mu are heterogeneous in length and sequence owing to the presence of host DNA²⁻⁶. The right end contains host sequences which vary between 500 and 3,200 base pairs (bp), while the left end heterogeneity was proposed to correspond to ~50-100 bp. To understand the mechanism by which a small amount of host DNA at the left end is packaged along with Mu DNA, we have now determined the precise lengths of these host sequences. The minimum size of the host sequences attached to the left end of the mature bacteriophage Mu DNA is 56 bp; host sequences longer than 144 bp are rare. The host sequences do not show a continuum from 56 to 144 bp but are rather packaged in discrete blocks. The first such block is 56-61 bp, the second is 67-72 bp and so on. Thus, each block represents fragments covering a 5-6-bp range, with a space of 5 bp between each block. It seems that Mu DNA is being measured in units of helical turns for packaging.

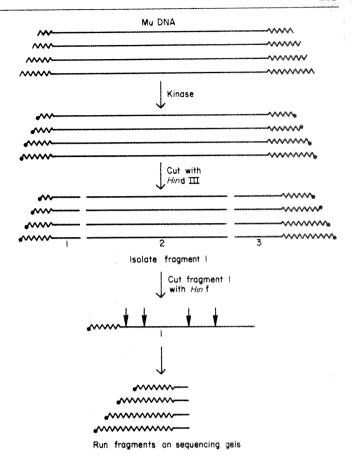

Fig. 1 The experimental design. A single line represents doublestranded Mu DNA. Wavy lines represent host DNA (not drawn to scale). Solid circles represent ³²PO₄ groups at the 5' ends of the DNA strands.

The ends of Mu DNA were labelled with ³²P using [y-³²P]ATP and polynucleotide kinase. Mu DNA was then digested with HindIII, which makes two cuts in the DNA, giving rise to three fragments. The 1,000-bp fragment containing the left end of Mu was isolated and cut with Hinf, which makes four cuts in the fragment, one of which is 7 bp from the left end of Mu. The digest was then run on a sequencing gel to size the molecules. The experimental design is shown in Fig. 1.

Figure 2 shows the results of the experiment. The smallest fragment obtained is 63 bp. As Hinf cuts 7 bp away from the Mu end, the minimum size of the host sequences at the left end must be 56 bp. As the largest fragments are in the range of 150 bp, the maximum size of the host sequences is ~144 bp. However, smaller fragments are much more frequent, and only a small minority of the fragments are larger than 100 bp, while fragments larger than 150 bp are extremely rare. The most striking feature of the size of the host sequences is that they are not present as a continuum from 56 to 144 bp, but rather appear in discrete blocks. Moreover, there is a regular pattern in which these blocks appear: the first block is from 63 to 68 bp; a gap of 5 bp is then seen, after which there is another block from 74 to 79. There are 10 such blocks, each one separated from the next by a 5-bp space, and each containing fragments covering a 6-bp range. This means that DNA cutting begins with a regular spacing of 5 bp but cutting can cover any of the next 5-6 bp. Analysis of the end nucleotides, by labelling of the end and analysis of the 5' nucleotide, showed that all four bases are present in equal amounts at both the left and right ends.

Two general modes of packaging of DNA into viruses have been recognized^{8,9}. One is site-specific packaging with some size constraints, such as the recognition of the ter sites of λ for packaging, and the other is the headful packaging, in which the size of DNA seems to have the predominant role. Packaging by a

headful mechanism was first proposed by Streisinger et al. 10 for phage T4, and has been shown to be a common mode of DNA packaging 5,11,12. However, the molecular mechanism of headful packaging is unclear. In context with Mu packaging, A.I.B. et al.3 discussed two alternative ways in which a small amount of host DNA can be packaged at the left end. In one mechanism, a specific site at the left end is recognized by a DNA cutting protein, the DNA is then cut to the left of the site randomly, and the cleaved DNA condensed into the heads being assembled. In

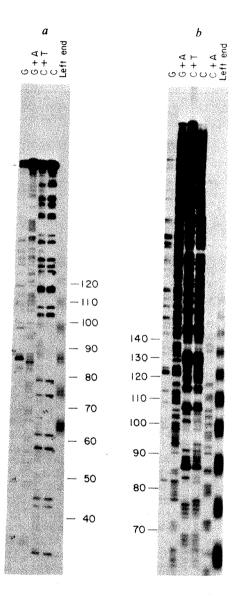

Fig. 2 Determination of the lengths of the left-end host sequences by electrophoresis in sequencing gels. Bacteriophage Mu particles were purified by a caesium chloride density gradient centrifugation. The DNA was extracted with phenol. To label the ends, the 5' phosphates were first removed by treating the DNA with alkaline phosphatase¹⁵. The ends were labelled using $[\gamma^{-32}P]ATP$ (>2,000 Ci mmol⁻¹) and polynucleotide kinase. The DNA was then cut with *HindIII* and the digest run on a 6% 1:40 acrylamide gel. The 1,000-bp left-end fragment was isolated¹⁵ and cut with Hinf. The digest (left end) was run on 8% polyacrylamide gels containing 7 M urea, together with DNA samples that were being sequenced; a and b are autoradiograms of 8% sequencing gels run for different times. The xylene cyanol dye marker was threequarters of the way down (a) or off (b) the gel. Portions of double-stranded DNA, labelled with ^{32}P at one 5' end, were partially cleaved at guanines (G), guanines and adenines (G+A), cytosines and thymines (C+T), cytosines (C), and cytosines and adenines (C+A), respectively, using the method of Maxam and Gilbert¹⁵. The numbers indicate the size of the fragments as seen on the sequencing gels.

the second mechanism, a packaging protein recognizes a specific sequence at the left end, the DNA is then folded and perhaps pushed into the heads being assembled, after which the DNA is cut at the left and right end.

It has been observed that the phage tail is attached at the right end of Mu^{13,14}; presumably, the right end is the last to be packaged, and the first to be ejected, suggesting that the left and right ends are being cut in different time and space. However, the minimum size of the host DNA at the left end is ~ 56 bp. It is difficult to reconcile this observation with the first mechanism in which the first event is cutting of the left end by an enzyme behaving like a type I restriction enzyme. The enzyme would have to recognize a site on the left end but start cutting only after 56 bp. As a working hypothesis, we favour the idea that the DNA is rolled or packaged first, in such a way that the first 56 host base pairs at the left end are not available for cutting. This could either mean that the left end is condensed first, and cut, after which the rest of the DNA is packaged in, or that the whole genome is packaged, and then the left and right end cuts are made.

How can we explain the regular spacing of the cuts? Note that the distance from the beginning of one block of 6 bp to the beginning of the second block is ~11 bp, which is about one turn of the double helix. It seems that the DNA is being measured for packaging, in units of helical turns. This measurement could be brought about by proteins that bind at each turn of the helix. The proteins perhaps cover one half of the turn so that only the other half is available for cleavage.

Errata

In the article 'IgG antibodies to phosphorylcholine exhibit more diversity than their IgM counterparts' by P. J. Gearhart et al., Nature 291, 29-34 (1981), Figures 1 and 2 were transposed.

In the letter 'Somatic and behavioural postnatal effects of fetal injections of nerve growth factor antibodies in the rat' by L. Aloe et al., Nature 291, 413 (1981), the received date was given as 7 November 1980. The paper was originally submitted on 7 November 1979; the date of receipt of the revised manuscript was 17 November 1980.

The cover caption for issue no. 5813 (28 May-4 June) of Nature was incorrect. The correct version from the authors is 'Homozygous (pigmented and unpigmented) progeny from heat-shocked eggs of heterozygous mothers'.

ATTERS ARISING

Sensory cues invalidate remote viewing experiments

TART, Puthoff and Targ1 have recently responded to our critical analysis^{2,3} of their evidence in favour of extrasensory remote viewing ability by reporting a rejudging of the original transcripts with all sensory cues removed. This yielded a high correlation between Price's descriptions and the target information. Furthermore. Tart et al. claim that the Marks-Kammann cueing explanation of remote viewing does not apply in principle to any of the replication experiments carried out after the series with Price.

The validity of the re-judging exercise for the Price series can be disputed on two counts. First, it should be noted that the editing of transcripts was carried out by one of the investigators (Tart). As Tart was himself aware of the correct targettranscript pairings, this could have led to biasing. Second, it is not permissible to include material for re-judging which has already been published or which may be available in some other form. A so-called 'blind' judge may have some memory of previously seen target-transcript matchings or have access to the published material. Only five of the series of nine targets and transcripts for which there is no normal or available method of matching except perceived similarity, could validly be used in re-judging. The remaining four transcripts should have been excluded, as in the unsuccessful rejudging exercise reported by us².

A much more serious problem with the response of Tart et al.1 to our report is their claim that sensory cues were not present in later experiments. Unfortunately, I have been unable to obtain a complete set of transcripts from SRI investigators despite frequent requests. However, in June 1977, Dr Arthur Hastings, who was a consultant to the SRI investigations responsible for judging experimental transcripts, allowed me to see six transcripts from the series with the subject H. Hammid, and I was far from satisfied with them as they contained sensory cues. A listing of targets in Hastings' possession correlating 0.83 (P < 0.01) with the order of target usage, together with transcript cues, would have provided an artefactual basis for correct target-transcript matchings.

Although Tart et al.1 conclude that SRI replication studies confirm the remote viewing hypothesis, serious methodological flaws throughout the experiments prohibit any such conclusion. The Targ-Puthoff researches conform to a long history in parapsychology of methodological flaws and mistaken conclusions. Unless proper controls and methods are used by impartial observers, the search for

scientific proof of paranormal and spiritual beliefs remains a futile enterprise.

Micrograzers may affect macroalgal density

THE EFFECT of density on plant growth and mortality has been recently discussed by Schiel and Choat1. Studying two species of large brown seaweed, Ecklonia radiata and Sargassum sinclairii, they found that high density had a positive effect, in contrast to data for terrestrial plants. They concluded that density affects marine and terrestrial plants differently, and suggested that these differences were due to protection from wave shock and the difference in plant-arthropod associations between terrestrial and marine environments. Uninjured brown algal thalli 1,700 contained up to copepods, amphipods and isopods.

Terrestrial plant density has a limiting effect on nutrient and water supplies to the individual plant that would not be expected for algal density, but we believe that the data for Sargassum and Ecklonia communities1 are exceptional and subject to reinterpretation. Specifically, conclusions on the general effect of density on marine plants should await data from algae typical of less exposed communities.

Our work on amphipod grazing in the field and in the Smithsonian Institution's coral reef microcosm demonstrates that coarser algae (for example, Hypnea) are protected from amphipod grazing by their size, but most filamentous species are heavily grazed². By eliminating epiphytes on coarser algae, amphipods increase growth rates of macroalgae such as Hypnea by as much as 300%. In subtidal areas, amphipod densities are kept low by fish predation³, but in situations where this is reduced by factors such as turbulence, micrograzer herbivory may be particularly important. Such high energy areas are characteristic habitats for brown algal macrophytes. Up to a point, densely growing Ecklonia and Sargassum plants would shelter more amphipods from predation. This would contribute to a positive effect of high density on these seaweeds, while being equivalent to a locust attack in its effect on many other algal species.

Schiel & Choat suggest that the study of marine plant-arthropod relationships could have important implications for mariculture. In fact, our work on amphipod grazing implies that maintenance of some amphipod species in mariculture facilities could increase yields significantly.

- 3. Young, D. K. & Young, M. W. J. mar. Res. 36, 569-593

SCHIEL AND CHOAT REPLY-Our recent paper1 reported two of our findings for large marine algae: (1) individual plants in dense, monospecific stands tend to be larger compared with plants of the same age in sparser stands, and (2) the number of crustagea in algal fronds may be quite high with no apparent adverse effect on algal plants. We contrasted this to terrestrial plant systems, where the opposite seems to apply in both cases. These observations were put forward as hypotheses worthy of further testing.

An experimental demonstration of a link between fish predators, frond-dwelling crustacea and the occurrence of epiphytes on large brown algal plants has proved largely intractable in field situations. Data on the comparisons of arthropod loads between densities and exposures of plants, the fish effect on arthropod loads, and the effects of arthropods on host plants are either lacking altogether or equivocal, particularly over large areas generally. Brawley and Adey² have provided evidence in their coral reef microcosm that such a link exists, and that high numbers of crustacea may be of benefit to larger algae by reducing epiphytism. Their results do not negate our hypotheses. Our argument admits the likelihood of a beneficial effect on plants, or no effect at all, due to crustacean loads. However, before a general case is made more data are required concerning: (1) the general effects of density on growth, survival and size of marine plants; (2) the effects of crustacea on marine plants, and (3) the effects of fish predators on crustacea. Brawley and Adey have provided some information. We welcome further testing of the hypotheses we have put forward.

The glass bead game

THE gap between theoretical and applied ecology seems to be widening. Indeed it is difficult to escape the worrying conclusion that some theoreticians are playing a version of Hermann Hesse's Das Glasperlen Spiel1 or that they have little feeling for or understanding of biological problems. A particularly good example is the recent article by Gurney et al.2 which attempts to provide a theoretical model to explain the oscillatory behaviour of laboratory populations of blowflies.

After reaching the esoteric conclusion that the blowfly cycles are "self-sustaining limit cycles" rather than "driven quasicycles", the authors proceed to use their model to explain the 'double-humped' nature of the cycles in terms of minimum population size (N_{\min}) in relation to the size at which the population achieves maximum reproductive success (N_0) . The mathematics are correct, but in their zeal, the authors fail to notice Nicholson's own explanation of the 'double-hump' phenomenon (see Fig. 3 legend in ref. 3). He says "the lack of a clear inverse relation between the various low adult densities and the number of eggs produced is due to the fact that adults are mostly senile as the adult minima are approached, near the minima many are newly emerged and incapable of laying eggs, and subsequently highly fertile young individuals dominate". In other words, the fact that breeding occurred in 'quasi-discrete' generations is probably almost entirely a consequence of age-specific variation in the reproductive performance of the adult blowflies. As Gurney et al. ignore this variation their model must be seen as artefactual and spurious—a product of the 'game'.

Of less importance, but still worrying, is the promotion of "a satisfying qualitative fit" in the conclusions to "good quantitative agreement" in the abstract, and the failure to refer to similar published work^{4,5}. In contrast, Readshaw and Cuff⁶ have published a biologically realistic model of Nicholson's results which includes readily identifiable parameters. An age-specific version of the model would undoubtedly simulate the 'doublehump' but the data are not yet available. J. L. READSHAW

- 6. Readshaw, J. L. & Cuff, W. R. J. Anim. Ecol. 49, 1005-1010 (1980)

GURNEY ET AL. REPLY-Readshaw raises three scientific objections to the model described in our recent article1. We shall deal with these in turn.

The question of the nature of the mechanism responsible for the observed cycles is very far from 'esoteric'. Any moderately repetitive fine structure exhibited by a limit-cycle type of fluctuation carries readily extractable dynamic information, whereas the fine structure of a driven quasi-cycle is mainly 'noise' which only serves to obscure our view of the underlying population dynamic. Thus our judgement that detailed investigation of the fine structure of the cycles observed by Nicholson is a worthwhile exercise hinges on our unambiguous demonstration that they are limit cycles.

It is clear from our work that if average future recruitment bears any kind of humped relationship to current adult population then cycles which have minima well below the population size at which maximum overall reproductive success is

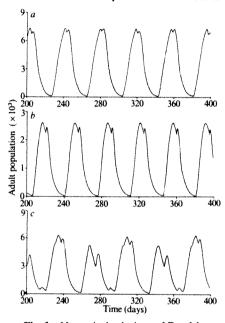

Fig. 1 Numerical solutions of Readshaw and Cuff's model equation⁴: n(t+1) = $0.8n(t) + R(n(t-\tau))$. a, Adult food-limited case: R = 10n when n < 171; R =1,795-0.503n when 171 < n < 3,569; R = 0 when n > 3,569. $\tau = 15$ days. b, Larval food-limited case: R = 10n(1- $\exp \{0.154-109.9/n\}$) when n < 714; R =0 when n > 714. $\tau = 13$ days. c, Adult food-limited case with modified parameters: R = 2.49n when n < 600; R =1,795-0.503n when 600 < n < 3569; R =0 when n > 3.569. $\tau = 15$ days.

achieved, must be accompanied by a 'discrete generation' pattern of breeding activity. A clear implication of Nicholson's^{2,3} batch culture results displayed in Readshaw and Cuff's paper4 is that just such a relationship exists for Lucilia cuprina, and there is thus no shred of evidence for their ex cathedra statement that the double-humped egg-laying rate curves observed by Nicholson are entirely the product of the age structure-dependent fecundity changes noted in Fig. 3 legend of ref. 3. However, such effects do provide a very plausible explanation of the observation that in four out of seven cycles shown the second peak of the double hump is considerably higher than the first.

The final objection of Readshaw is the claim that the fine structure predicted by our model must be 'spurious and artefactual' because their 'biologically reasonable' model predicts a limit cycle with no fine structure. This claim has no sound basis. Their model is effectively identical to ours except in the details of the functional form chosen for the recruitment rate function. In both experimental regimes considered the form chosen has a single hump with a maximum at a population size (N_0) comfortably in excess of the observed minimum population and thus there seems every reason to suppose that careful numerical analysis will reveal that their model predicts population cycles with a fine structure very similar to that shown in Fig. 6 of our paper¹. Figure 1a, b shows that this is indeed the case. Furthermore, in the adult food-limited case (Fig. 1a) note that there is no direct experimental evidence for the value of N_0 implied by the parameters chosen by Readshaw and Cuff (171) and indeed that this value is considerably below the value of 600 that may be deduced from Nicholson's data (see Fig. 3 of ref. 3). If we abandon the attempt to force Readshaw and Cuff's piecewise linear approximation to the recruitment function to fit the behaviour of the population as $N \rightarrow 0$ and instead place the maximum of the curve somewhere near the correct value (Fig. 1c), then the structure predicted by their model becomes very strong indeed.

We conclude that the very simple mechanism proposed in our original article captures much of the spirit of the population dynamics underlying Nicholson's blowfly cycles and is thus a contribution to narrowing (rather than widening) the gap between theoretical and applied ecology. W. S. C. GURNEY

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

BOOK REVIEWS

Unravelling the threads of cosmic history

James N. Fry, Craig Hogan and David N. Schramm

CLASSICAL physical cosmology, as exemplified by texts such as Weinberg's Gravitation and Cosmology (Wiley, 1972), deals with an idealized "smooth" Universe taken as a whole, its overall dynamics and mean composition. General relativity describes the universal expansion in an average sense, assuming that the material content is very nearly uniform. All standard calculations, such as the synthesis of primordial helium, rely on this background. Astronomers, on the other hand, have always studied discrete concentrations of matter, the galaxies for example, but until recently many regarded cosmology as a "study of the search for two numbers" - the expansion rate and the deceleration parameter of the smoothed substratum.

However, the detailed study of the distribution of galaxies, their clustering and their peculiar (non-Hubble) motions, forms a fascinating subject in its own right, which offers a great variety of problems, dynamical, statistical and observational, for both the astronomer and the physicist. Here there exists the possibility of unravelling some of the threads of cosmic history. Jim Peebles has written the first textbook to deal almost exclusively with what might more appropriately be described as the "in-between-scale structure of the Universe" - bigger than galaxies, but much smaller than the observable Universe.

On the very largest scales, above about 10 Mpc (30 million light years), the Universe is indeed nearly uniform, as is indicated by such diverse measures as the isotropic distribution of galaxies, faint radio sources, the X-ray background radiation, and especially the microwave background radiation, which of all these comes from farthest away and reflects the oldest parts of the Universe we can reach its last interaction with matter probably occurred when the Universe was about 1,000 times smaller than it is now. On smaller scales, less than 10 Mpc, the distribution of galaxies displays a rich structure, illustrated in the frontispiece of Peebles's book and also in a beautiful poster ("One Million Galaxies" published by Peebles and Stewart Brand of CoEvolution Quarterly). The structure can be quantified by statistical measures such as the galaxy correlation functions, and it is consistent with the model that galaxies are distributed in a sort of self-similar nested

The Large-Scale Structure of the Universe. By P. J. E. Peebles. Pp.416. ISBN hbk 0-691-08239-1; ISBN pbk 0-691-08240-5. (Princeton University Press: 1981.) Hbk \$30, £18.10; pbk \$9.95, £6.20.

hierarchy — galaxies are bound in groups which orbit each other in clusters and so on, up to scales of 3-10 Mpc where the largest aggregations blend smoothly into the uniform background.

From its gravitational effects on luminous galaxies, we now know that most of the mass of the Universe is dark. We cannot tell from these dynamical studies what the mass is made of, although there are some constraints from big bang nucleosynthesis on the total baryonic component. Depending in part on how the total cosmological mass density compares with these constraints on baryon density, the dark matter might be anything from swarms of invisible particles, such as neutrinos, to clusters of very dim, low mass stars, to black holes as large as a million solar masses each. Nevertheless, if the distribution of mass is similar to the visible galaxy distribution then natural mechanisms exist for creating a hierarchical structure. (One must be careful here, since there is some evidence that the dark matter may have a different spatial distribution from the light-emitting matter.) In one picture, as the Universe expands and cools, galaxies (with their dark counterparts) condense out of the primordial matter. Neighbouring galaxies gravitationally pull each other out of the expansion and start orbiting each other, forming groups; neighbouring groups approach each other, and so on. Opposed to this is an alternative view — that the first scales to condense are very large, about 10 Mpc, and that flattened gas clouds of this size ("pancakes") fragment into smaller ones, which break up into still smaller ones, and so on, finally reaching galaxy sizes. Both frameworks seem viable and are intuitively satisfying. It remains a fascinating enigma exactly how a nearly uniform expanding Universe produces the structure we see. This area of cosmology is at an interesting stage of development because, although the expanding Universe option is widely used, various detailed models (to explain the same observations) differ in almost all essential aspects. Fortunately, the differing predictions are on the verge of being tested, primarily by

observations of anisotropy in the microwave background, our best direct probe of the epoch just prior to galaxy formation.

Peebles's book supplements the standard textbook version of cosmology with the results of these structural studies. If you are active in research dealing with cosmological structure, you must have a copy, for it is the most complete source for finding out what has been done. However, for those with only casual interest, the book is much less effective. The approach is that of a pioneer in the field, recollecting calculations and lines of thought from over the years, and it is thus extremely valuable as a reference: but this does not make for ideal pedagogy. Except for the historical introduction, there are few pointers in the 400 pages toward which material is likely to remain important; current fashion and fundamentals are treated with almost equal weight. If you know specifically what you want to know, you can find it in this book - unlike Peebles's previous book, Physical Cosmology (Princeton University Press, 1973), it does have an index; every standard calculation is here (there are four frameworks for deriving the linear growth equations) and there is an extraordinarily complete list of references. But if you are an outsider and want to get a picture of what is going on, what is likely to remain relevant and what may be tossed out in the next ten years, you will probably be lost.

Peebles does not attempt to conceal his biases, and exercises the author's right to present a convincing case — with a fair assessment of the uncertainties. He emphasizes the idea of a "well-regulated", quiescent initial state replacing the formerly popular ideas of primordial chaos, turbulence, magnetic fields; the hierarchical clustering picture emerges as the one simple physical process which can make solid predictions about the galaxy distribution; the Universe contains a lot of unseen matter, possibly enough to make the daring statement $\Omega = 1$.

Despite the possible shortcomings, there is no question that the field has needed this book. It will undoubtedly become a standard graduate extragalactic astronomy textbook. Here is a collection of useful calculations which were not previously available in any one place (although some of the book overlaps with S. M. Fall's excellent review on correlation functions (Rev. Mod. Phys. 51, 21; 1979). Even

though there is no complete universal model, there is a great deal of standard lore—correlation functions, newtonian statistical dynamics, relativistic perturbation theory, scaling laws and so on. Peebles avoids the fundamental uncertainties by focusing on manageable physical problems

which can be solved to yield precise answers to specific questions. That is perhaps the best that anyone could do given our present state of ignorance.

The authors are at the Astronomy and Astrophysics Center of the University of Chicago.

Rabbie Burns and the art of genetics

Tony Searle

Genetics and Probability in Animal Breeding Experiments. By Earl L. Green. Pp.271. ISBN 0-333-27243-9/0-19-520159-0. (Macmillan Press, London/Oxford University Press, New York: 1981.) £20, \$36.95.

IT is well known that even "the best laid schemes o' mice an' men gang aft a-gley", so the need for this book is obvious. It is meant to minimize the "a-gley factor" where the two species undertake joint genetic enterprises, and it should fulfil its purpose if read as conscientiously as the lectures engendering it were doubtless listened to. They were given by Earl Green when Director of the Jackson Laboratory, to each year's new crop of staff members and postdoctoral fellows. No one who is familiar with the high standards of genetic

research and animal breeding at that laboratory can doubt their effectiveness.

Amidst all the marvels of somatic cell hybridization, probes, DNA sequencing and the like, the more humdrum procedures of constructing and maintaining inbred strains for particular purposes, introducing mutant genes into them, studying newly arisen mutants and finding where they belong in the genome must go on. In the past, the necessary expertise has had to be acquired piecemeal and often belatedly; now it is all gathered together in one volume. I could have done with such a vade-mecum 30 years ago, but it (and I) would have been slimmer then. Thus, there is now full coverage of how to produce and use recombinant inbred strains, which have proved so valuable in recent years, and of modern methods of linkage analysis. In fact, the chapters "Linkage, Recombination and Mapping" and "Mating Systems", with associated appendices (for example on maximum likelihood methods) take up nearly half the book.

J.B.S. Haldane used to punctuate his genetics lectures with "Let me give you an example" and Earl Green uses the same idea liberally in this book. Matings of mice with pale ears and dilute coats illustrate probabilities, tests of significance, symbolism, gametic output and so on, other matings illustrate linkage and still others demonstrate the use of Finney's scores for linkage and analysis. These help a lot in what would otherwise be a harder slog. All the examples are based on mice but of course the book as a whole should be a boon to all mammals in search of a genome. The mouse is far ahead of the rest at present, but with modern mutagenic methods the gap could be narrowed quite rapidly.

Among the ten appendices are the complete rules of nomenclature for mouse genes and inbred strains, as well as the author's system of record-keeping and a recommended mouse-room layout. My only regret is that there is so little on how to deal with translocations and other chromosome anomalies. There are a lot of them about nowadays and, with some types of cross, they can play havoc with Mendelian genetics.

A.G. Searle is in the Genetics Section at the Medical Research Council's Radiobiology Unit, Harwell.

Spectroscopic sound

M. J. Adams

Photoacoustics and Photoacoustic Spectroscopy. Chemical Analysis, Vol. 57. By Allan Rosencwaig. Pp.324. ISBN 0-471-04495-4. (Wiley: 1981.) £19, \$43.75.

THE photoacoustic effect (prior to 1977 more commonly termed the optoacoustic effect) provides the basis for a calorimetric method of measuring the absorption of electromagnetic radiation by a sample under study. The phenomenon may be applied to many spectroscopic and nonspectroscopic studies involving the interaction of radiation with matter. Dr Allan Rosencwaig, internationally recognized as a pioneer in the modern development of photoacoustic techniques, has attempted to bring together in this book a comprehensive review of the theory and current applications of methods employing the effect.

In the first two chapters the author presents a brief summary of the phenomenon and describes its study up to the last decade. Until quite recently the majority of applications of photoacoustic spectroscopy (PAS) have been limited to the study and analysis of gaseous systems, and six chapters (approximately a quarter of the book) are given over to this work. The theory and more common experimental arrangements for gaseous PAS are discussed and a chapter is devoted to a review and evaluation of suitable radiation sources for PAS. Applications of PAS to the study of gases, including multicomponent analysis, de-excitation studies, high resolution spectroscopy, photolysis and non-linear effects, are examined.

Much of this first part of the book is already available in many excellent reviews and serves here only as a background and introduction to the remainder of the text which covers the application of photoacoustic studies to the examination of condensed-phase media. It is in the contents of these 15 chapters that the author's own contributions are predominant and which provide the book with its special interest. A chapter is devoted to the general theory of the photoacoustic effect employing gas-microphone systems and piezoelectric transducers, and another, of five pages, provides a simplified theoretical account for those who might find the more rigorous treatments, derived in previous sections, demanding. Experimental systems and apparatus for the examination of solid and liquid samples are reviewed and a chapter is reserved for the more novel spectroscopic studies, including dichroism and Fourier transform techniques. The areas of condensed-phase sample PAS reviewed comprise chemical studies, surface studies and applications in biology and medicine. De-excitation phenomena in solid and liquid media, including fluorescence

No.12 on Reader Enquiry Card.

studies and quantum efficiency measurements, are discussed in detail. There is also a useful account of thermal processes in samples and sample depth profiling, and thickness measurements using the photoacoustic effect are considered. The final two chapters of the book are concerned with more specialized instrumental topics: photoacoustic spectroscopy at low temperatures and photoacoustic microscopy.

During the past decade studies involving the photoacoustic effect have increased dramatically and the range of instrumental methods and applications is now widespread. In producing this book, the first of its kind to deal exclusively with photoacoustics, Dr Rosencwaig has succeeded in including a discussion of all the major topics currently being investigated employing the techniques. With its wide-ranging coverage, the text will be of interest not only to those actively engaged in photoacoustic research but also to spectroscopists seeking a detailed introduction to the technique and its possible use in their own field.

M.J. Adams is in the Department of Spectrochemistry at the Macaulay Institute for Soil Research, and is a past SRC Research Fellow in photoacoustic spectroscopy.

Earliest technology

J.A.J. Gowlett

Premiers Outils Taillés D'Afrique. By Hélène Roche. Pp.263. ISBN 2-901161-146. (Société d'Ethnographie, Paris: 1981.) 80F. Available from C. Klincksieck, 11 rue de Lille, Paris 7.

"FEEL good" wrote Johanson in his diary just before discovering the early hominid remains of "Lucy". It was good too that Hélène Roche, a French co-worker in the same Afar region of Ethiopia, succeeded in finding the earliest stone tools yet known (c. 21/2 million years old), which now gain mention in a book of wider scope. Her book, though, is not so much the popular introduction which the title might imply, but rather a painstaking exercise in the study of early stone technology. English texts on early man abound, but a book in French is rarer, and deserves to find an audience. Central questions are approached thoughtfully: "What is the significance of the acquisition of tools in the process of hominization?" is an issue too often swept aside by currently favoured theories which stress social factors, such as food sharing, in human evolution. Here, in contrast, the flaked stone tools, which preserve sequences of individual decisions from the distant past, are seen as an important aspect in early man's progress, encouraging technical awareness, aptitude

The heart of the book is a statistically

presented examination of the manufacturing routines employed in fashioning "worked pebbles". It seems a pity that some key sites, including those at Afar, are treated only in the useful introductory chapters, and that the main study hangs on just two samples from Olduvai and two from insecurely dated sites in Morocco – but then, nobody has access to material from all the early sites.

There are some debatable points of terminology or fact (Australopithecus africanus has not been found at Baringo), but Roche is surely right to criticize prehistorians for continuing to use terms like "chopper" even though we now intend no functional implication.

Roche concludes that simple tools were fashioned by using only certain preferred flaking sequences, amongst a range of possible routines, thus showing a consistent human desire to "get out" a worked edge from the raw material. But could they have been made differently? Some workers will argue that a worked pebble can only end up in certain forms. Nevertheless, Roche makes perceptive points about early human conceptual abilities, and her book offers much food for thought.

J. A. J. Gowlett is Senior Archaeologist of the Radiocarbon Accelerator Unit, Research Laboratory for Archaeology and the History of Art, Oxford.

Notes on the birth of experimental psychology

O.L. Zangwill

An Education in Psychology: James McKeen Cattell's Journal and Letters from Germany and England, 1880–1888. Edited by M.M. Sokal. Pp.372. ISBN0-262-19185-7. (MIT Press: 1981.) \$30, £18.60.

WILHELM Wundt (1832-1920), an unsuccessful physiologist who held the Chair of Philosophy at the University of Leipzig for many years, is remembered as the founder of the first laboratory explicitly dedicated to the pursuit of experimental psychology. It opened in 1879 and soon began to attract graduate students from all over the world - and in particular from the United States - drawn it would seem less by the profundities of Wundt's thought than by the promise of his laboratory. Accordingly, it was to Leipzig that a 20-year-old American graduate, James McKeen Cattell, the son of a Presbyterian Minister who was also Principal of the College from which his son had graduated, directed his footsteps.

Cattell studied under Wundt for two years. He then returned to America and for a year held a teaching post at Johns Hopkins University, which however he relinquished in order to return to Leipzig and to become, largely at his own initiative. Wundt's assistant. Their work at this time was largely concerned with the measurement of reaction times, then a very popular preoccupation of psychologists and which has in recent decades regained much interest as a result of contemporary concepts of human information processing. Cattell's work was published in both German and British journals (including Mind and Brain). He obtained his doctorate at Leipzig in 1886 and spent the greater part of the next two years at St John's College, Cambridge, which has a long-standing reputation as an institution sympathetic to experimental psychology.

Cambridge had at that time no Department of Experimental Psychology and a proposal set in train by James Ward in 1877

that a psychophysics laboratory be instituted was vetoed as disrespectful to the dignity of mind. While unable to proceed further with his experiments on reaction time and associative processes, Cattell's iournal and letters report exciting discussions with philosophers such as Ward and Henry Sidgwick, neurologists such as Ferrier and Hughlings Jackson and, most significant of all, the polymath Sir Francis Galton. Indeed in his year or two at Cambridge Cattell acquired from Galton a major interest in the measurement of individual differences in mental capacity which owed nothing to his years with Wundt and which did much to shape his work at Columbia in the earlier decades of this century.

This selection from Cattell's journal and letters, mostly to his parents, together with some of their replies, provides an interesting picture of the impact of Europe on a sensitive and intelligent young American psychologist in the penultimate decade of the last century. While some of his judgements, particularly on matters aesthetic, are naive in the extreme, others reflect an intellectual dedication and whole-hearted devotion to science which might well have led to much more important original research had the young author decided to act on his original plan to remain permanently in Cambridge. (As it was, Cattell's later career was largely that of an organizer of research and an academic administrator, and he cannot be rated as in the top flight of American psychologists of his period.) The material has been assembled and edited with scholarship and care, though it is perhaps a pity that many passages labelled as 'gossip'' have had to be excluded. If one's interest lies in the man rather than in his work, which appears to be the case here, his gossip may provide much more interesting clues to his character than the details of his work, his travels and his social encounters with the distinguished.

None the less, some interesting items of social history escape the editor's scissors. For example, it is evident that self-experiments with a whole variety of drugs, including caffein, ether, hashish, laudanum and morphine, were regarded as perfectly in order even in the family of a Presbyterian College President. Such "experiments" appear to have been regarded as healthy explorations of the

range of consciousness and as carrying no social or medical stigma whatsoever. It would be interesting to trace the reasons why such widely disseminated personal idiosyncracies apparently failed to produce anything remotely approaching the student drug culture of today.

O. L. Zangwill is Professor of Experimental Psychology at the University of Cambridge.

Transformations in magma physics

M.J. O'Hara

Physics of Magmatic Processes. Edited by R.B. Hargraves. Pp.585. ISBN hbk 0-691-08259-6; ISBN pbk 0-691-08261-8. (Princeton University Press: 1980.) Hbk \$40, £24; pbk \$15, £9.30.

This companion volume to Evolution of the Igneous Rocks; Fiftieth Anniversary Perspectives (Princeton, 1979) emerges from a conference commemorating the fiftieth anniversary of Bowen's great publication. Written by an impressive list of experts, it contains 11 chapters on a range of aspects of the physics, thermochemistry and trace element chemistry of magmas.

In the opening contribution, P.C. Hess discusses the structure of silicate liquids and indicates the importance of its influence on liquid immiscibility and distribution coefficients for trace elements. His account, though useful, would have been more valuable with the inclusion of the instructive saga of the variations of nickel distribution between olivine and liquid, and if the implications of changes in liquid structure with pressure (and with time in an experiment) for measured distribution coefficients had been surveyed in more detail.

D.F. Weill, R. Hon and A. Navrotsky next illustrate the progress made, despite considerable difficulties, in the prediction of crystal-liquid phase equilibria from thermodynamic data. In this context, it is worthy of note that experimental determination has a more important future than some would have predicted five years ago. Progress in determination of the important physical parameters of magmas is covered by I. Kushiro. He emphasizes the importance of the transition from four-fold to six-fold coordination of aluminium in controlling increase of density, decrease of viscosity and change of liquid structure in the 10-20 kb range. (The mind leaps to the possible effects of the same transition in the coordination of silicon, which should produce yet more dramatic changes of such properties at pressures encountered within the lower part of the upper mantle — it is a pity that Kushiro does not speculate on this.) He does, however, discuss the overall implications of the changes of viscosity and density for rates of magma movement, changes in volatile solubility and the efficiency of magma extraction, crystalliquid fractionation and diffusive processes.

S.R. Hart and C.J. Allegre review the field of trace element and isotope geochemistry, before going on to provide an excellent summary of the "traditional" (or pre-1980) theory of the petrogenesis of mafic and granitic rocks. The more complicated but entirely plausible trace element models (touched on briefly in this chapter), combined with new understanding of the physics of magma mixing, have transformed thinking on the subject; fractionating magma chambers fed by uniform parent liquids can erupt lava suites which must (traditionally) be interpreted as partial melting products of heterogeneous mantle sources. The rehabilitation of assimilation and contamination is at hand, and increasing evidence for diffusive differentiation of trace elements (and isotopes?) in magma chambers may shortly overwhelm all other considerations. These are stirring times!

In his critical review of problems in heat flow determination and interpretation, E.R. Oxburgh concentrates on a survey of partial melting in upward convecting systems. Somewhere in this book it would have been appropriate to refer to the vexed question of density constraints on mantle plumes and to the inverse possibility that partial melting at the base of the mantle precedes and drives the convective motions. An unconsidered possibility is that partial melts may become denser than olivine (but not denser than a bulk residue containing silica-rich garnet rather than pyroxene) near the base of the upper mantle, hence allowing upward motion of low percentage partial melts, downward movement of high percentage melts and complex redistribution of heat-producing elements.

Whereas the first five chapters are models of clarity, H.R. Shaw's contribution is distinctly tough going. In almost mystic prose he explores possible relationships between stress fields, rates and volumes of magma flow, and seismicity. Nevertheless, I shall be reading and re-reading this section in order to understand its implications for the (rather neglected) situations where major magma chambers intervene between source and vent, and changes in magma composition

and density may become key factors in controlling magma transport. In the following contribution, F.J. Spera covers some of the same ground as Shaw but extends the discussion to many other aspects of the segregation, ascent and eruption of magmas. Major evolution of liquid composition probably occurs between source and point of eruption in most volcanic systems, and will complicate further the relationships discussed here.

In a thoughtful and stimulating contribution, T.N. Irvine documents the recent revolution in ideas concerning chemical and physical processes in slowly cooled magma chambers. This will be essential reading for anyone interested in consolidation of magmas. Irvine covers diagenesis of crystal accumulations but unfortunately only touches on fluid dynamics; it is in this latter field that some of the most spectacular progress has been made since the book went to press.

A.W. Hoffman deals with one- and two-way diffusion in magmas, making particular reference to determinative methods rather than specific applications. One of the most important questions which is discussed in detail by Hoffman concerns the possible influence of diffusion through the boundaries between individually wellmixed convecting layers in a cooling magma chamber. While crystal-liquid equilibria apply a constraint on the lowest layer — at least if the chamber is solidifying by bottom-crystallization - it does not follow that the higher layers of the magma from which lava flows are likely to be derived will be in major- or trace-element equilibrium with the "cumulate" assemblage, or even in isotopic equilibrium with it.

E. Dowty deals with the basic theory of crystal nucleation and growth. He reviews a range of factors which may affect the morphology and chemistry of growing (or dissolving) crystals, and thus the development of grain size distributions and textures of igneous rocks, stressing once again the value of experimental work. G. Lofgren continues the story of the experimental study of crystal growth and texture development, especially with regard to lunar and terrestrial basic magmas. This final contribution provides a timely review of recent activities in the field.

Like its companion volume, this book appears at the moment when igneous petrology is making its most rapid advances since Bowen's day. Consequently it, too, suffers from omissions which will prevent it from standing as a milestone on the long road towards our understanding of magmatic processes; rather, it should be appreciated as a speedometer. Nevertheless, I found the book stimulating reading and recommend it to all serious students of igneous petrology.

M.J. O'Hara is Professor and Head of the Geology Department, University College of Wales, Aberystwyth.

ANNOUNCEMENTS

Awards

The 1981 recipients of the Harvey Prize of the Technion — Israel Institute of Technology are Prof. Sir James Lighthill (Provost of University College, London, UK) receives the Harvey Prize in Science and Technology; Prof. Hans W. Kosterlitz (Director of the Unit on Addictive Drugs, University of Aberdeen, UK) receives the Harvey Prize in Human Health.

The winners of the 1981 General Motors Cancer Research Foundation Awards are Dr Wallace Prescott Rowe (Chief of the Laboratory of Viral Diseases at the National Institute of Allergy and Infectious Diseases in Bethesda. Maryland) for his contributions to virology; Dr E. Donnall Thomas (Director of Medical Oncology at the Fred Hutchinson Cancer Reseach Center in Seattle, Washington) for developing bone marrow transplantation as a successful treatment for acute leukemia and aplastic anemia: Dr Cesar Milstein (Medical Research Council Laboratory of Molecular Biology in Cambridge, UK) for developing hybridoma technology; Dr Takashi Sugimura, (Director of Tokyo's National Cancer Center Research Institute) for identifying possible cancer causing substances in our food.

The Low Temperature Group of the Institute of Physics has awarded the Simon Memorial Prize to **Prof. A. J. Leggett** (University of Sussex), for work on the theory of superfluid ³He.

The Trustees of the Lady Tata Memorial Trust have made international awards for research in leukaemia to: Dr B. Azzarone (Italy), Dr A.D. Crockard (UK), Dr S. Venuta (Italy) — renewed awards. Dr H.D. Abrams (USA), H.J. Allen (UK) — new awards.

The International Meteorological Organization (IMO) Prize, for outstanding work in meteorology or operational hydrology and international cooperation has been awarded to **Prof. Bert Bolin** (Director of the International Meteorological Institute, Stockholm).

The Beit Memorial Fellowships for medical research 1981 have been awarded to David Leonard Bentley (MRC Laboratory for Molecular Biology, Cambridge, UK); Stephen Eric Kearsey (MRC Laboratory for Molecular Biology, Cambridge, UK); David Ian Vaney (The Physiological Laboratory, Cambridge University, UK); John Vincent Priestley (Dept of Pharmacology, Oxford University, UK); Peter John Richardson (Dept of Clinical Biochemistry, University of Cambridge Medical School, New Addenbrooke's Hospital, UK).

Meetings

21-22 August, Excitation-Contraction Coupling in Skeletal, Cardiac and Smooth Muscle, Banff (Dr George B. Frank, Dept of Pharmacology, The University of Alberta, Edmonton, Alberta, Canada T6G H77).

25-27 August, Life Sciences in the Service of Alaska, Fairbanks (Conferences and Institutes, The University of Alaska, Fairbanks, Alaska 99701, USA).

2-4 September, Modern Aspects of Phase Equilibria, Teesside (Mrs M. Findley, Dept of Chemical Engineering, Teesside Polytechnic, Borough Rd, Middlesborough, Cleveland, UK).

1-7 September, Fundamentals of Microprocessors, London (Course Registrar, Bleasdale Computer Systems Ltd, Francis St, London SW1, UK).

6-12 September, 32nd International Astronautical Congress, Rome (Prof. Luigi G. Napolitano, International Astronautical Federation, 250 Rue Saint-Jacques, 75005 Paris, France).

7 September, Water Quality, London (R. Gardam, Thames Water Authority, New River Head, Rosebury Avenue, London EC1, UK).

7-8 September, Chemical Aspects of Changes in Food on Storage, Norwich (Dr R. Fenwick, Society of Chemical Industry, Food Group, 14 Belgrave Square, London SW1, UK).

7-10 September, **EMAG '81**, Cambridge (The Institute of Physics, 47 Belgrave Square, London SW1, UK).

7-11 September, Chemistry of Carbocations, Bangor (Dr J.F. Gibson, The Royal Society of Chemistry, Burlington House, London W1, UK).

7-11 September, An Introduction to Hydrometallurgy, Hatfield (D.B. Firth, Institution of Chemical Engineers, 12 Gayfere St, London SW1, UK).

10-11 September, National Conference on Fitness and Aging, Washington DC (U.A. Wheaton, President's Council, 400-6th Street S.W. Room 3030, Washington DC 20201, USA).

16-18 September, Chemical Engineering Education, London (C.J. Bullock, Chemical Engineering Dept, Teesside Polytechnic, Middlesbrough, Cleveland, UK).

17-18 September, Regulation of Energy Balance, Edinburgh (Dr J.A. Milne, Hill Farming Research Organisation, Penicuil, Midlothian, UK).

19-21 September, Teilhard and Metamorphosis, Arizona, (Arcosanti-Events, 6433 Doubletree Rd, Scottsdale, Arizona 85253, USA).

22 September, Autonomic Nerves of the Gut, London (Dr M. Daly, Glaxo Group Research Ltd, Ware, Herts, UK).

22-24 September, Royal Society of Chemistry Autumn Meeting, Leeds (Dr J.F. Gibson, The Royal Society of Chemistry, Burlington House, London W1, UK).

23 September, Information Meeting for Nature Protection Societies from the European Community, Brussels (Ms J. White, EEB,31 rue Vautier, B-1040 Bruxelles, Belgium).

23-25 September, Wave and Tidal Power, Cambridge (Conference Organiser, Wave and Tidal Energy, BHRA Fluid Engineering, Cranfield, Bedford, UK).

24-25 September, Platinum Group and Gold Mineralization, Ultramafic Rocks, and Zeolites, Manchester (Dr C.M.B. Henderson, Dept of Geology, The University, Manchester, UK).

24-25 September, The World Conservation Strategy and the European Communities, Brussels (Ms J. White, EEB, 31 rue Vautier, B-1040 Bruxelles, Belgium).

25-28 September, Eocene and Oligocene of the Isle of Wight, Sandown (Dr A.N. Insole, Museum of Isle of Wight Geology, Sandown Library, High St, Sandown, Isle of Wight, UK).

28 September — 2 October, Annual Meeting European Society of Nuclear Methods in Agriculture, Aberdeen (Mr A.H. Knight, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, UK).

28 September — 2 October, **Dynamics of Turbid Coastal Environments**, Nova Scotia (D.C. Gordon, Marine Ecology Laboratory, Bedford Institute of Oceanography, PO Box 1006, Dartmouth, Nova Scotia, Canada B2Y 4A2).

28 September-17 October, New Approaches to Plant Genetics and Breeding, Peking (Dr O.L. Gamborg, International Plant Research Institute, 887 Industrial Rd, San Carlos, California 94070, USA).

29 September, Gas Cyclones, London (Mrs E.H. Edwards, Institution of Chemical Engineers, 12 Gayfere St, London SW1, UK).

30 September — 2 October, **Deburring'81**, New Orleans (J. Slaughter, Technical Activities Dept, Society of Manufacturing Engineers, 1 SME Drive, PO Box 930, Dearborn, Michigan 48128, USA).

2-3 October, 21st Anniversary Meeting of Radiologists, Dublin (Miss A. Daly, Faculty of Radiologists, Royal College of Surgeons in Ireland, 123 St Stephens Green, Dublin 2, Ireland).

5-7 October, Wind Energy Conference and Workshop, Washington (Conferences Group, SERI, 1617 Cole Boulevard, Golden, Colorado 80401, USA).

5-8 October, Pollution Control, Brighton (NSCA, 136 North St, Brighton, Sussex, UK).

The Mammals of North America

2nd Edition, Vol. 1, Vol. 2, and Set

by E. Raymond Hall, Museum of Natural History, University of Kansas

A complete update of this monumental reference, with summaries of the latest taxonomical studies of North American native mammals of the post-Columbian period makes this two-volume encyclopedia an incomparable guide to the more than 3,600 named mammals inhabiting the region from Greenland to Panama. It contains 546 original maps, 634 drawings of skulls, 187 drawings of typical mammals, detailed measurements, and brief comparisons of closely related species.

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

GRADUATE RESEARCH ASSISTANT

Applications are invited for a graduate research assistant to work with Dr K R Bruckdorfer on the distribution of cholesterol in and between cell membranes. The post, which is supported by the SERC, is on Scale 1B.

Further particulars may be obtained from the School Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP (telephone 01-837 5385 ext. 54), to whom applications with curriculum vitae and the names of two referees should be sent by 24 July 1981. Please quote ref. SRC/B. (9024)A

CLEVELAND CHIROPRACTIC COLLEGE

FACULTY POSITION IN ANATOMY

Full time faculty position is available in the Department of Anatomy beginning in October, 1981. Principal responsibilities include lectures and laboratories in Gross Histology, Anatomy, Embryology.

Applicants must hold the PhD or masters degree in the specific discipline and have a strong committment to teaching.

Send curriculum vitae and names of three references by August 1, 1981 to: Director of Basic Science, Cleveland Chiropractic College, 6401 Rockhill Road, Kansas (NW739)A Missouri 64131

INSTITUTE OF CANCER Research: A post-doctoral post is available for a period of three years in the Division of Cell and Molecular Biology, Chester Beatty Research Institute, Fulham Road, SW3, (Head, Dr R A Weiss). The project involves the study of the genetics of neoplastic transformation using cellular and molecular genetic techniques. Experience in somatic cell genetics, cell biology or molecular genetics would be advantageous although not essential. Starting salary in range £6,070 to £6,880 pa plus London Allowance of £967 pa. Further information may be obtained from Dr C J Marshall, Tel: 01-352 8133, ext 262. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 300/G/5. (8997)A

WASHINGTON STATE UNIVERSITY

FACULTY FOR INSTITUTE OF BIOLOGICAL CHEMISTRY

An outstanding scientist is being sought to fill a permanent faculty position in the Institute. This person will be expected to conduct a vigorous research program in biological chemistry relevant to agriculture and participate in graduate teaching. Salary and rank are open to negotiation. Review begins September 1,

Send nominations and applications, including a curriculum vitae, a short description of research goals and a list of three or more references to P E Kolattukudy, Director, Institute of Biological Chemistry, Washington State University, Pullman, Washington 99164.

Washington State University is an equal opportunity/affirmative action employer. (NW735)A

Tring Museum, Hertfordshire **Ornithologist**

The Tring Meseum contains the ornithological collections of the British Museum (Natural History), made up of skins, skeletons, eggs, nests and liquidpreserved specimens. Each of these classes of material serves different research needs and presents different curatorial problems.

This is a new appointment, created to ensure long term continuity in the output of high quality research. The successful candidate will carry out research in the broad field of avian systematics and evolution, and will plan and develop long term innovatory programmes, combining conventional techniques with new ones such as computer studies and biochemical analysis. There will be opportunities for field

and overseas.

British Museum

work, both in the UK

Candidates, normally aged under 32, should have a 1st or 2nd class honours degree in Zoology or Biology and at least 4 years postgraduate experience in ornithology.

Appointment as Senior Scientific Officer £7,640 - £9,615 (salaries under review) with starting salary according to qualifications and experience.

> For futher details and application form (to be returned by 31 July 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: SB/68/DK. (9017)A

> > (Natural History)

AGRICULTURAL RESEARCH COUNCIL MOLECULAR GENETICIST

required in the Biochemistry Department to join a newly-established team that will apply recombinant DNA techniques to the programme of research into infectious diseases of farm animals. Appointment will be at Higher Scientific Officer (Salary Scale £6,075 to £7,999 per annum) or Senior Scentific Officer (Salary £7,644 to £9,619 per annum) level. (Currently under review).

Qualifications required are a 1st or Upper 2nd class honours degree in Biochemistry, Microbiology or related subject, together with (at HSO level) at least 2 years' and (at SSO level) at least 4 years' postgraduate research experience in a relevant area of molecular biology or

Non-contributory pension scheme. Pleasant working conditions in rural environment. Hostel accommodation available for single person.

Application forms from the Application forms from the Secretary, Institute for Research on Animal Diseases, Compton, Newbury, Berks RG16 0NN quoting ref: 467. Closing date: 24/7/81.

(9018)A

POLYTECHNIC OF CENTRAL LONDON School of Engineering and Science Division of Life Sciences LECTURER IN MARINE BIOLOGY (3 year contract post from

1 September, 1981)
Applications are invited from suitably qualified candidates for the post of Lecturer II in Marine Biology. The successful candidate will be expected to teach both basic and applied aspects of marine biology in undergraduate and postgraduate courses. A good background in biological sciences is desirable as some general undergraduate teaching in biology is also required.

Candidates should possess a good Honours degreee and preferably a higher degree. An active interest in research and proven research ability would be a recomendation. Salary: on scale £7,221 — £11,190 p.a. inclusive of London Allowance

Application forms and further details can be obtained from The Establishment Officer, The Polytechnic of Central London, 309 Regent St., London W1R 8AL. (Tel: 01-580 2020 ext. 212). Closing date: 29 July 1981. (9006)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from uitably qualified persons for ippointment to the following positions:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES DEPARTMENT OF NEUROBIOLOGY

RESEARCH FELLOW/ SENIOR RESEARCH FELLOW

Applicants should have experience in Neurobiology, with preference tovards vision or analysis of arthropod entral nervous system. Closing date: 12 August 1981.

Term of appointment for Research Fellow/Senior Research Fellow up to hree years with the possibility of extension to five years.

Salary an appointment will be in accordance with qualifications and experience within the ranges: Research Fellow \$A19,821 — \$A25,871 p.a.; Senior Research Fellow \$A27,684 — \$A33,021 p.a. Current exchange rate: \$A1 = JK£0.54NP.

Reasonable travel expenses are said and assistance with housing is given for an appointee from outside Canberra. Superannuation benefits tre available from applicants eligible to contribute. The University eserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should btain the further particulars from he Registrar, PO Box 4, Canberra ACT 2600, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF before ubmitting. (9039)A

HEAD OF PARASITOLOGY DEPARTMENT

A senior appointment for a leading Biochemist

The Wellcome Research Laboratories at Beckenham in Kent is the main centre for the Research activities of the Wellcome Foundation Limited — the British based parent company of an international organisation concerned with pharmaceutical and biological products.

The Parasitology Department numbers some 40 people including 10 Scientists and is concerned with basic research, biological screening and drug development in fields relevant to human and veterinary medicine. The department is part of the experimental biology division which is also concerned with research into molecular biology and immunology.

Our need is for a Scientist with substantial experience of the biochemistry of parasites — preferably in relation to their chemotherapy. He or she must possess a record of personal research achievement and demonstrate the ability to direct research in this field.

For this important post, we offer a substantial salary which will fully reflect the responsibility of the role plus a valuable range of fringe benefits including 5 weeks holiday, pension and sick pay schemes and assistance with relocation to the London or Kent area, where appropriate.

Please send a detailed curriculum vitae quoting ref WRL/132 to The Pesonnel Manager, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR33BS.

Wellcome

POSTDOCTORAL POSITION

available. Research on hepatic microsomal electron transport and fatty acid elongation and desaturation.

Contact: Dr Dominick L Cinti, University of Connecticut Health Center, Department of Pharmacology, Farmington CT 06032.

An Affirmative Action/Equal Opportunity Employer. (NW734)A

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY Picosecond pulsed raman studies of adsorbates

Applications are invited, from chemists or physicists, for a postdoctoral

SENIOR RESEARCH ASSISTANT

for three years from as soon as possible, to study the applications of picosecond pulsed lasers in obtaining Raman spectra of strongly fluorescing adsorbed species or adsorbents. This is a new technique and a new picosecond laser system will be available. Some experience is lasers is desirable.

Initial salary in the range £6,070 to £6,880 on Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 31 July, 1981 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars are available. (9055)A

POSITION of "Full Professor of Physical Chemistry" is open at the Technical University of Graz (succession Prof. Dr. Karl Torkar). Applicants (German speaking) should submit their résumé by October 31, 1981 to Dean, Technisch-Naturwissenschaftliche Fakultät, Technische Universität, Graz, Petersgasse 16, A-8010 Graz (Austria). (W376)A

BROCK UNIVERSITY DEPARTMENT OF BIOLOGICAL SCIENCES GENETICIST

Tenure stream position in the Department of Biological Sciences, Brock University, at the Assistant Professor level is available from January 1, 1982 or earlier. The appointee will be expected to teach molecular, transmission and population genetics at the undergraduate level, to develop an independently funded strong research program, to supervise graduate students and to interact with the faculty over several levels of biological organization. Although specific research speciality is open, research areas of particular interest include microbial genetics, eucaryotic genetics (including mammalian molecular genetics) and population genetics. Canadian applicants will be considered first.

Submit complete curriculum vitae by October 31, 1981, with a statement of research and teaching experience, reprints of published papers, names of three referees to Dr MS Manocha, Chairman, Department of Biological Science, Brock University, St Catharines, Ontario, Canada L2S 3A1. (NW733)A POSTDOCTORAL POSITION—Enzyme mechanisms and models, design of transition state analog inhibitors. Candidate should have experience in two of the following: enzyme purification, immunology and organic synthesis. R V Wolfenden, Dept of Biochemistry, University of North Carolina, Chapel Hill, NC 27514. UNC is an equal opportunity/affirmative action employer. (NW742)A

QUEEN ELIZABETH COLLEGE Kensington

(University of London)
DEPARTMENT OF MICROBIOLOGY

POST-DOCTORAL RESEARCH ASSISTANT

Required for an SERC-funded project tenable for three years which involves an investigation of the reactions of bacterial cytochrome oxidases with oxygen and other ligands using low temperature dual-wavelength and flash photolysis techniques. Applicants should be recently qualified PhD graduates. Previous research experience in bioenergetics, microbial biochemistry and/or enzymology would be advantageous, but not essential.

Starting salary: £7,073, inclusive of London Weighting. Starting Date: 1 October 1981, or as soon as possible thereafter.

Further details can be obtained from Dr R K Poole, Department of Microbiology. Applicants should send a curriculum vitae and names of two referees to Mrs J Staight, Queen Elizabeth College, Campden Hill Rd, Kensington, London W8 7AH.

(9034)A

Apply Your Microbiological Expertise in Cosmetics

Surrey

As one of the U.K.'s largest and best-known perfumery and cosmetics companies, Lentheric Mornay's extensive range of popular products has a considerable weight of research, testing and analysis behind it.

Our well-equipped microbiological laboratory makes a considerable — and continuous — contribution to these investigations, and we are currently looking for a qualified man or woman with appropriate industrial experience to assume responsibility for all routine aspects of sampling and analysis associated with microbiology. In addition the Microbiologist will undertake ad hoc assignments in close liaison with our Research and Development, Marketing and Production departments, especially challenge testing for all new products.

Facilities at our centralised premises are first class, and you will enjoy a competitive salary together with a full range of benefits including pension scheme and the use of our subsidised canteen and staff shop.

To find out more contact Paul O'Bryan, Personnel Department, Lentheric Morny Limited, Vale Road, Camberley, Surrey. Tel: Camberley 62181.

·LENTHÉRIC MORNY

THE UNIVERSITY OF ADELAIDE WAITE AGRICULTURAL RESEARCH INSTITUTE

invites applications for a LECTURER (LIMITED TERM) (S8481)

in the Department of Agronomy for up to two years from 1 January 1982 to undertake research and to lecture in aspects of crop physiology/agronomy. Preference will be given to applicants with a field orientation and who would interact with present staff undertaking research in crop physiology, crop nutrition, pasture utilization and plant breeding. Applicants with interests in grain legumes, continuous cropping, minimum tillage or use of agricultural chemicals are encouraged to apply.

Further enquiries about the duties attached to the position may be directed to Professor C J Driscoll, Department of Agronomy, Private Bag, Glen Osmond, South Australia 5064.

Salary: Lecturer $$A19,182 \times 7 - $A26,037$ with optional superannuation provision.

The Conditions attached to the appointment may be obtained from the Registrar.

Applications, in duplicate, giving full personal particulars, details of academic qualifications, (including citizenship) and names and addresses of two or three referees, should reach the Registrar of the University, GPO Box 498, Adelaide, South Australia, 5001 not later than 15 August 1981. (9036)A

UNIVERSITY OF BRISTOL

SRC supported

SRC supported POST-DOCTORAL RESEARCH ASSISTANT

to work on characterisation of the light requiring enzyme NADPH:Protochlorophyllide oxidoreductase. Experience in protein purification and sequencing or DNA isolation and characterisation desirable but not essential. Post to commence 1st September, 1981.

Details from Dr W T Griffiths, Department of Biochemistry, University of Bristol BS8 1DT. (9026)A

THE UNIVERSITY OF MANCHESTER FOETAL EPITHELIAL PHYSIOLOGY

Applications are invited for the post of

TEMPORARY LECTURER

held jointly between the Departments of Physiology and Child Health. Research will be on ion transfer across the placenta mainly in sheep or pigs. Teaching duties will be in the Department of Physiology. This is a new venture and the initial appointment will be for a term of three years. The possibility exists for the appointment to be made substantive if the joint appointment is a success. Initial salary range pa: £6,070 — £7,290.

Particulars and application forms (returnable by September 1st) from the Registrar, The University, Manchester M13 9PL. Quote ref. 127/81/N. (9004)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF HISTOLOGY & CELL BIOLOGY

TECHNICIAN (GRADE 3)

to assist with a research project. Work concerns cell biology, primarily preparing material for electron microscopy. Minimum qualifications ONC, but might suit graduates in an appropriate discipline.

The post is available for approximately 18 months. Salary in a range £4,672 — £5,473 per annum.

Application forms available from the Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref. RV/842/N. (9023)A

UNIVERSITY OF LONDON Institute of Obstetrics and Gynaecology

A vacancy exists for a RESEARCH ASSISTANT

with Biochemical training or experience, for a project on placental transfer and metabolism of amino acids in relation to normal and abnormal foetal growth.

The starting salary on the 1B scale will be £5,285 plus £969 London Allowance.

Applications, with CV and the names of 2 referees to: Dr D L Bloxam, Institute of Obstetrics and Gynaecology, Queen Charlotte's Maternity Hospital, Goldhawk Road, London W60XG. (9007)A

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF MICROBIOLOGY LECTURESHIP

Applications are invited from men and women for a Lectureship in Microbiology, financed initially by the SRC under their Special Replacement Scheme. Conditions of service, including probation and tenure, as for other University lectureships.

Initial salary up to £7,290 a year on scale rising to £12,860 a year. Expected age of candidate would be up to 27 years but older candidates not precluded.

Starting date will be as early as can be arranged. The successful candidate will be expected to fulfil all the normal duties of a lecturer and to have an enthusiastic commitment to research.

Preference to candidates with experience in molecular biology or microbial genetics.

Further details available from the Registrar and Secretary, the University, Sheffield S10 2TN, to whom applications (including) curriculum vitae, publication list, teaching experience, research interests and three referees) should be sent by 31 July 1981. Quote ref: R 604/G. (9044)A

UNIVERSITY OF NOTTINGHAM

FACULTY OF
AGRICULTURAL SCIENCE
RESEARCH ASSISTANT IN
APPLIED PHYSICS

Applications are invited for a Research Assistant to work in the Food Science laboratories of techniques for measuring the viscosity of food and biopolyme systems at high temperatures. This will be a challenging project in which there is considerable industria interest

The post, which is funded by the SRC will be available for a three year period. There will be an opportunity to register for a higher degree.

Applicants should possess or hope to obtain a degree in Physics of Chemical Engineering.

The salary will be in the range £5,285 to £6,070. Application: including a curriculum vitae and the names and addresses of two referees should be sent to Dr J R Mitchell Food Science Section, Dept o Applied Biochemistry and Nutrition School of Agriculture, Suttor Bonington, Nr Loughborough. Please mention

nature

when replying to

these advertisements

Director, Research & Development

Consider this unique opportunity to apply—and develop—your expertise with an exciting and growing company in biomedical research, development and production.

You'll provide creative and organizational direction to biochemistry, biology and bioengineering groups conducting a wide variety of research and development activities in support of the creation of collagen-based medical products. You and your organization will explore the fields of cell biology, extracellular matrix biochemistry and mitogen physiology with the ultimate business goal of developing products used in repairing, replacing or regenerating human body tissue.

To accomplish these ambitious goals you'll provide direction to the development of unique biomaterials, analytical test methods and instruments which will lead to a wide range of product candidates. You will be expected to maintain a continuing relationship with the scientific community through the generation and presentation of technical papers, and to direct an active program designed to produce invention reports.

The ideal candidate is expected to be a well published scientist with the ability to inspire and maintain scientific excellence. An important requirement is a PhD in biochemistry or biology or an MD with a research orientation. Approximately ten years of related experience including research managerial assignments is required. Experience with protein biochemistry, cell biology or immunology is highly desirable.

We offer an exciting and creative environment and our salary and benefits are highly competitive. We are confident you will also find our equity participation program attractive.

For consideration please submit a comprehensive resume to Dr. Bruce Pharriss, Vice President, Scientific Affairs, Attn: Department D, Collagen Corporation, 2455 Faber Place, Palo Alto, CA 94304. An affirmative action employer.

A(967WN)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PLANT SCIENCES

Applications are invited for a post of

POSTDOCTORAL RESEARCH FELLOW

1 the Department of Plant Sciences or work on the isolation and haracterization of fertilization eceptors from marine algal gametes. Experience in immunological techiques will be a particular advantage. The appointment will be made for a ixed period of up to one year and six nonths.

Applicants should have, or shortly spect to receive, a PhD, preferably in the area of cell surface biohemistry (plants or animals).

Salary within the range £6,070 — 7,290 on the IA scale for Research nd Analogous Staff.

Informal enquiries may be made to or L V Evans or Dr J A Callow telephone 0532 31751 ext. 6576 or 580).

Application forms and further particulars may be obtained from the tegistrar, The University, Leeds LS2 JT, quoting reference number 53/7/D. Closing date for applications 0 July 1981. (9014)A

University of Edinburgh RESEARCH TECHNICIAN

required to work in the Department of Molecular Biology, Kings Buildings, on a project concerning the molecular genetics of insertion sequences in bacterial plasmids. An HNC or equivalent qualification in an appropriate subject is required. Salary on scale £5,695 — £6,650. Appointment to take effect from September 1981 for a period of up to three years. *Ref: NT794*.

Application forms may be obtained from the Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS. Tel: 031-556 2930. (9030)A

ARMAGH OBSERVATORY Armagh, Northern Ireland Applications are invited for the post of RESEARCH ASTRONOMER

tenable from 1st January, 1982.

Salary will be at an appropriate point on the University Lecturers' scale £6,070 to £12,860 pa according to qualifications and experience.

Applications stating qualifications, publications, research proposals, and names of three referees should be received not later than October 31, 1981 by the Secretary, Armagh Observatory, Armagh BT61 9DG, N Ireland, from whom further particulars may be obtained. (8994)A

ROYAL FREE HOSPITAL POST DOCTORAL FELLOW Salary on scale: LAI requir

£6,472 — £10,562 p.a. inc. Applications required from biochemists to work on DNA synthesis associated with leukaemia research.

The appointment is for a postdoctoral fellow for one year in the first instance, which may be extended to three years.

Applicants should apply in writing to Professor A. V. Hoffbrand, Department of Haematology, Royal Free Hospital, Pond Street, Hampstead, London NW3.

(9005)A

JUNIOR MEDICAL LABORATORY SCIENTIFIC OFFICER

required to start in September in busy, small histological research laboratory. Ideal post for school leaver wishing to embark on career in medical laboratory technology. In addition to histology, varied duties include photography, illustrations, filing and general laboratory running. Day release granted for relevant studies. Minimum requirements: English, Maths and 2 relevant sciences at GCE 'O' levels.

Application forms from Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP. (Tel: 01-352 8121 Ext. 4164).

(9009)A

POSTDOCTORAL INDIVIDUAL with cell biological and biophysical interests for work on cellular factors controlling translational mobility of molecules on surfaces and/or within the cytoplasm of living cells. The work will involve the following techniques: fluorescence recovery after photobleaching (FRAP or FPR), fluorescence microscopy and image analysis, and biochemical and cell biological methods. Contact: Dr Ken Jacobson, Laboratories for Cell Biology, Department of Anatomy, University of North Carolina, Chapel Hill, NC 27514. Tel: 919-966 5703. An Equal Opportunity/ Affirmative Action Employer.

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London) A TECHNICIAN

is required to work in the Academic Department of Surgery in the Royal Free Hospital at Hampstead. The successful candidate will assist with teaching duties and research work and experience of biochemistry or tissue culture would be essential. Qualifications: HNC or Degree.

Salary on scale £5,204 — £7,124 inclusive (under review). 34 days leave including public and customary days. 37 hour week.

Application forms (and further particulars) are available from the School Secretary, RFHSM, 8 Hunter Street, London WCIN 1BP or telephone 01-837 5385 ext. 10. Closing date: 24 July 1981. Reference T/S. (9012)A

Attention: Biomedical Researchers

FUNDING HELP OFFERED

We represent major pharmaceutical companies willing, under certain circumstances, to provide three kinds of funding for promising biomedical innovations:

- Development funding. Provided in return for an option to purchase or right of first refusal.
- 2) Marketing funding. Provided under a suitable licensing/royalty agreement.
- 3) **Venture capital.** Provided under highly selective, special conditions.

PRI serves as a clearing house for these companies, evaluating innovations on their behalf and recommending those we consider worthy of action. The companies pay our fees; there are no fees charged to innovation sources.

For full details, please write Marion C. Gold, Product Resources International, Inc., 800 Third Avenue, New York, New York 10022. Make no disclosures (except for issued patents) until you have read the material.

(NW730)A

City Hospital

SENIOR CYTOGENETICIST Full-time. BASIC GRADE CYTOGENETICIST

Full-time.

The above appointments are in the South-Trent Sub-Regional Cytogenetics Service currently housed in the Maternity Unit at the City Hospital, Nottingham, but will shortly be moving to more extensive accommodation on the same site.

The successful applicants will be expected to share in all standard laboratory procedures including culturing, harvesting, slide making, staining and appropriate analysis of preparations from blood, amnistic fluid, bone marrow and other tissues. The diagnostic workload is heavy but it is hoped that, with these two new appointments all members of staff will have some time for personal work. One post is available immediately and one from 1st October, 1981.

For the Senior Grade post, preference will be given to those candidates with a wide range of experience in diagnostic chromosome analysis.

For the Basic Grade post, a graduate with a reasonable degree in one of the Biological Sciences is required. Preference will be given to candidates whose degree course or postgraduate work includes a large Genetics component and/or tissue

Further information about these posts can be obtained by ringing Dr Pat Cooke on Nottingham (0602) 608111 Extension 2785 or by visiting the Department.

Application forms are available from Personnel Services, Valebrook House, Sherwood Hospital, Hucknall Road, Nottingham. Tel: (0602) 625459 anytime.

Closing date: 30th July, 1981. (9040)A

NORTH NOTTINGHAM HEALTH DISTRICT(T)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF
VETERINARY ANATOMY
Re-advertisement
Applications are
invited for the post of
RESEARCH ASSOCIATE

in the Department of Veterinary Anatomy to work on an ARC funded project on postnatal muscle development in the pig. The project is for three years starting on 1st September, 1981.

Applicants should have a good degree in Veterinary Medicine, Zoology, Agriculture or a related subject. The successful applicant will have the opportunity to register for a higher degree.

Applications, before 24th July 1981, together with a curriculum vitae and the names of two referees, should be sent to Dr N C Stickland, Department of Anatomy, Royal (Dick) School of Veterinary Studies, Edinburgh EH9 1QH, from whom further particulars may be obtained. Please quote Reference 5022.

KING'S COLLEGE London

DEPARTMENT OF BIOPHYSICS POSTDOCTORAL RESEARCH ASSISTANTS

- 1) Biochemist with experience in nucleic acid and protein chemistry or enzymology to study the mechanism of chromatin transcription in vitro. Post tenable for 2 years from 1 September 1981. Salary in the range £6,070 to £8,515 plus £967 London allowance. USS.
- 2) Cell Biologist or Biochemist with experience in tissue culture and recombinant DNA techniques to study the structure and expression of cloned genes in eukaryotic cells. Post tenable for 2 years from 1 September 1981. Salary in the range £6,070 to £9,335 plus £967 London allowance, ISS

Please reply as soon as possible, with a curriculum vitae and the names and addresses of two referees, to Dr H J Gould, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2B 5RL. (9051)A

MLSO specialising in Microbiology required in the Aerobiology Unit Cardiothoracic Institute, Bromptol Hospital, Frimley, Surrey. Wori involves investigation of occupational hazards associated with microorganisms and includes preparation of antigens and other immunological procedures. Applicants should hold HNC MLSA or equivalent. Experience in isolation and identification methods for fungi and knowledge of microbial biochemicatechniques desirable. Starting salar £4,677. Application forms availably from the Secretary, Cardiothoraci Institute, Fulham Road, Londo SW36HP. (9019)A

QUEEN ELIZABETH COLLEGE Kensington

(University of London)

MICROBIAL BIOELECTROCHEMISTRY POST-DOCTORAL RESEARCH ASSISTANTS

Applications are invited for two SR supported post-doctoral Researc Assistantships to work in a bit technology group on the development of microbial fuel cells an reactors. One post is for an electric chemist and the other for a microbia physiologist. Salary £6,070 p (minimum) plus £967 London Allow ance. The posts are available from October 1981, or as soon as possible and are tenable for 3 years.

Enquiries to Dr H P Bennette Department of Chemistry. Applications with curriculum vitae an names of two referees should be ser to Mrs J Staight, Assistant Secretary Queen Elizabeth College, Campde Hill Road, Kensington, London W 7AH. Closing date for application 31 August 1981. (9033)A

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH BIOSTATISTICIAN

pplications are invited from MSc aduates for the above post.

The incumbent will be involved in atistical aspects of research projects id surveys covering a wide field inuding, inter alia, epidemiology, incer, nutrition and immunology.

Computer facilities are available at the opportunity exists for obtaining a higher degree.

We offer: a competitive salary plus rvice bonus equivalent to 93% of ne month's salary, subsidised medal aid, Pension fund and 30 days ave per annum.

Address applications, including irriculum vitae, to: Head, Person-il Services, SAIMR, PO Box 1038, hannesburg 2000, Republic of buth Africa. (W374)A

WO POSTDOCTORAL positions e available immediately in an active NS-pharmacology laboratory. Onping research projects include: Mechanisms of modulation of ansmitter release; 2) Pre- and postnaptic mechanisms of action of etylcholine, neuroactive peptides nd other putative transmitters; Spinal mechanisms in pain and nalgesia; 4) Synaptic mechanisms in euronal plasticity. The first position suitable for a well-trained and athusiastic neurophysiologst/ europharmacologist capable of irrying out intracellular studies on ammalian central neurones. The cond position is for an imaginative surochemist who is interested in a++ and transmitter release, alysis of presynaptic membrane ructure, Ca++ binding proteins, c. Salary is negotiable. Send irriculum vitae and names of three ferees to: Dr B R Sastry, Departent of Pharmacology, Faculty of ledicine, The University of British olumbia, 2176 Health Sciences lall, Vancouver, BC, V6T 1W5, anada. (NW737)A

INIVERSITY OF ABERDEEN DEPARTMENT OF ENGINEERING RESEARCH ASSISTANT

pplications are invited from raduates in chemical or mechanical agineering, chemistry or physics for two-year post as a Research ssistant to work in a group engaged a materials behaviour. The accessful applicant will be oncerned with the erosive/prrosive effects of hot, (about 90°C) quid flowing through nozzles made f various types of steels and nickel.

The work is sponsored by the K Atomic Energy Authority, ounreay. Consideration will be ven to new or recent graduates. arting salary on Scale IB — £5,285 - £7,700.

Further particulars from The scretary, University of Aberdeen, ld Aberdeen with whom applicaons (2 copies) should be lodged by I July 1981. Ref. No. JAM/1.

(9013)A

VICTORIA UNIVERSITY OF WELLINGTON

New Zealand

LECTURESHIP IN PHYSICS (2 Posts)

Applicants for these positions should have proven excellence in research and must be able to contribute effectively to the Department's undergraduate teaching programme, which covers all the main branches of physics.

The appointees will be required to participate in the Department's research activities. These are concentrated in three fields: Condensed Matter Physics (experimental and theoretical studies of interfaces and of optical and transport properties of metal alloys and amorphous materials), Geophysics (geomagnetism, plate tectonics, seismology, vulcanology, marine geophysics, physical oceanography) and Nuclear Physics (low-energy nuclear Physics (low-energy nuclear techniques applied to material, medical and environmental studies).

For the first post the Department is seeking to appoint a person who, in addition to satisfying the above criteria, has experience in the use of microprocessors and computers in experimental physics, and could contribute to the development of a course in the physics and applications of micro-processors. Additional preference would be given to an applicant who could help establish links between existing research groups.

For the second post preference will be given to those with research interests in Geophysics who would help establish links with other research groups. An appointee in Geophysics may also become a member of the University's Institute of Geophysics.

The salary range for lecturers is NZ\$19,140 to \$23,520 per annum.

Conditions of appointment may be obtained from the Appointments Officer of the University or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 15 October 1981. (9045)A

SWISS INSTITUTE FOR EXPERIMENTAL CANCER RESEARCH

Applications are invited for an associate scientist appointment to participate in an established research project in experimental hematology/oncology, with particular emphasis on regulation of cell differentiation and drug action on cells in culture. Some years of post-doctoral experience in the field, as evidenced by published work, are desired.

This staff position is non-tenured with a 3 to 5-years contract. Starting date: January 1st, 1982 + 2 months.

Applications with curriculum vitae and names of two references to be sent to: Chief of personnel, Swiss Institute for Experimental, Cancer Research, Ref: O/N. 1066 Epalinges/Lausanne, Switzerland.

Closing date: September 10, 1981. (W372)A

Biochemists

Smith Kline & French Research Limited is the U.K. based research group of the international SmithKline Corporation. We are currently undertaking a phased expansion of our research activities as part of the move to a new 39-acre site at The Frythe near the village of Welwyn. This new facility, which is nearing completion, represents a major investment and will be totally dedicated to pharmaceutical research and development.

We have two vacancies for biochemists to join a group working on interesting and varied projects investigating the role of histamine on the brain.

The first position is suitable for a person of graduate or equivalent status, and will involve measurement of enzyme and neurotransmitter levels. Applications are encouraged from newly qualified graduates and from persons with previous experience in this area.

The second position is suitable for a recently qualified Ph. D. or equivalent. The successful applicant will have a strong interest and previous experience in the study of enzymes, not necessarily in the brain. The position is concerned mainly with investigation of aspects of neurotransmitter synthesis, catabolism and turnover.

We offer competitive salaries on incremental scales; commencing salaries will be for newly qualified graduates £5800 per annum and for Ph. D's £7500 per annum. We operate flexible working hours, and benefits include free life assurance amounting to three times annual salary, an excellent contributory pension scheme, discretionary annual bonus and membership of BUPA. A generous relocation grant is available if appropriate.

Please telephone for an application form, quoting the Ref. No. NAT/166 to:

Marie Alpar, Recruitment Administrator,

SMITH KLINE &FRENCH RESEARCH LIMITED

Mundells, Welwyn Garden City, Hertfordshi⊪e AL7 1EY. Tel: Welwyn Garden 25111 Ext 4651.

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

LECTURER/SENIOR LECTURER IN CIVIL ENGINEERING

(Geotechnology)
LECTURER/SENIOR LECTURER IN GEOLOGY
(Geochemistry and Isotope Geology)
LECTURER/SENIOR LECTURER IN GEOLOGY
(Metamorphic and Structural)
LECTURER/SENIOR LECTURER IN GEOGRAPHY AND
GEOGRAPHICAL EDUCATION.

Salary Scales:

Senior Lecturer £9,688 × 364 — 10, 780 × 373 — £12,645 Lecturer Grade I £8,777 × 364 — £10,233 Lecturer Grade II £4,836 × 348 — £6,574 × 364 — £8,396

Appointments on these scales according to qualifications and experience. Both permanent pensionable terms and short-term contracts are offered for academic posts.

Further particulars on the posts, on conditions of service and on method of application should be obtained, prior to submitting an application, from the Director, Appointments and Personnel, University of Zimbabwe, PO Box MP 167, Mount Pleasant, Salisbury, Zimbabwe, or from the Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF.

Closing date for receipt of applications for all posts 31 July 1981.

Post Graduate/Post Doctoral Research Geologists/Environmental Scientists

The Universities of Cambridge and East Anglia hope soon to be able to appoint two Geologists/Environmental Scientists (1st or upper 2nd class degree) to post-graduate/post-doctoral research positions in connection with a 2-3 year joint research project on Global Palaeonvironments sponsored by the British Petroleum Company Limited Research Centre, Sunbury-on-Thames.

Applications should be submitted as soon as possible both to Professor B. M. Funnell, School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, and to Dr. A. G. Smith, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ.

Further particulars may be obtained from either Professor Funnell, tel: Norwich (0603) 56161 or Dr. A. G. Smith, tel: Cambridge (0223) 355463.

(9047)A

Technische Hogeschool Delft

The Faculty of Chemistry and Chemical Engineering of the Delft University of Technology invites applications for the position of

Full Professor of Biokinetics

Biokinetics, other bio-sciences and technology are being integrated to establish a biotechnology group and thus teaching and research in biokinetics have to be directed to biotechnological application. Close cooperation with colleagues working in biotechnology will be required.

Teaching: The professor will be responsible for lectures and/or courses in Systems Analysis, and Kinetics of Microorganisms and their Active Compounds, possibly Irreversible Thermodynamics of Biological Systems. The supervision of experimental work carried out by undergraduate and graduate students will also be involved.

Research: The research task will be concerned with the development and testing of mathematical models to describe enzyme systems and the growth of and product formation by microorganisms This research will be performed in cooperation with colleagues working on biotechnology and will be directed to industrial processes and environmental control.

Administrative duties: The successful applicant will be expected to participate actively in the administrative tasks of the Biotechnology group and the Faculty.

Additional information will gladly be supplied by the Chairman of the Appointing Committee.

Applications, including a curriculum vitae, full detail of qualifications, experience and the names of at least two referees should be addressed to the Chairman of the Appointing Committee, Prof. N. W. F. Kossen, c/o Bureau van de Afdeling der Scheikundige Technologie, Postbus 5045, 2600 GA Delft, The Netherlands. Closing date for applications is 15th August 1981. (W375)A

ST JUDE CHILDREN'S RESEARCH HOSPITAL

DIVISION OF **IMMUNOLOGY**

MOLECULAR AND CELL **BIOLOGY**

Postdoctoral research traineeships are offered in a multidisciplinary research institute. (1) Biochemistry: structure and functions of biological membranes; biological regulation mechanisms with emphasis on hormonal action; receptor functions of normal and neoplastic growth and cellular messengers; and control (W Y Cheung, M Morrison and G Schobaum); (2) Immunology: regulation of antibody formation; macrophage functional heterogeneity and characterization of macrophage receptor functions and structures (F L Adler, M Fishman and W S Walker); (3) Pharmacology: human and animal cancer chemotherapy; drug-induced changes in DNA replication and repair synthesis; genetic, biochemical and physiological approaches to analysis of mechanisms of drug resistance in human cells (T P Brent, A Fridland and A Welch), and (4) Virology: molecular biology and epidemiology of viruses; eukaryotic gene expression and regulation (A Granoff, D Kingsbury and R G

Applicants must be citizens or permanent residents of the US. Please send curriculum vitae, names of three references and a brief statement of career objectives to Dr M Fishman, Division of Immunology, St Jude Children's Research Hospital, 332 N Lauderdale, PO Box 318, Memphis TN 38101

UNIVERSITY **OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY**

Applications are invited for a postdoctoral research position to investigate the molecular genetics of bacterial plasmids. Experience ir this area, and particularly in plasmic DNA manipulation, is desirable. The appointment becomes available this autumn, and will be for one to three years. Salary will be on Research Range 1A.

Applicants should send a CV, references and a letter describing their research interests to Dr N S Willetts. Department of Molecular Biology, University Edinburgh, Edinburgh EH9 3JR. Please quote Reference 5031.

Postdoctoral Research Associates BROOKHAVEN NATIONAL LABORATORY

Two Postdoctoral Research Associate positions will be available in October, 1981, in the Biology Department at Brookhaven Laboratory.

One position is for study of photosynthetic mechanisms of nitrogen reduction heterocysts of cyanobacteria. Optical and EPR spectroscopic techniques are applied to isolated heterocysts and photosynthetic membrane pre-parations. A PhD in plant physiology or biochemistry, with experience in photohydrogen production, nitrogen fixation or hydrogen assimilation research, preferably in cyanobacteria, is desirable.

The other position is for study of electron flow and energy conversion mechanisms in higher plant photosynthesis. Techniques used include optical and EPR spectroscopy of intact chloroplasts and isolated membrane complexes. A PhD in biochemistry, plant physiology or biophysics, with experience of bioenergetic and electron transport systems, preferably in photosynthesis, is desirable

Initial appointments will be for one year, at a minimum salary of \$14,000 per year, with possibility

Candidates should send résumé and names of three referees to Dr Geoffrey Hind, Biology Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, Long Island, NY 11973.

Aberdeen

SCHOOL OF MECHANICAL AND OFFSHORE ENGINEERING **RESEARCH FELLOW**

Materials scientist for major research project on marine corrosion and fouling of North Sea oil and gas installations, financed by SERC Marine Technology Directorate. RGIT's marine corrosion research group collaborates with University of Aberdeen marine biologists and zoologists and with offshore industry. The appointment will be for one year in the first instance.

Salary range £6,070 to £6,880 with appropriate placing according to qualifications and experience.

Details from Secretary, Robert Gordon's Institute of Technology, Schoolhill, Aberdeen AB9 (9043)A

Yale University

DIRECTOR

PEABODY MUSEUM OF NATURAL HISTORY

Applications are invited for the position of Director of the Museum at the rank of full professor, and with appointment (according to field) to the Departments of Biology, Geology and Geophysics or Anthropology. Yale University is seeking a scholar of international reputation who will develop interdisciplinary research and teaching programs in the natural sciences through the Peabody Museum and the affiliated academic departments.

Applications, including a curriculum vitae and the names of three references, should be sent to Professor Keith S. Thomson, Dean of the Graduate School of Arts and Sciences, Yale University, P.O. Box 1504A, Yale Station, New Haven CT 06520. Closing dates for applications - September 30, 1981.

Yale University is an equal opportunity, affirmative action employer.

(NW744)A

POSTDOCTORAL POSITIONS available for study of mechanism of linear DNA replication. Send CV and names of to references to Dr Junetsu Ito, Department of Molecular and Medical Microbiology, College of Medicine, The University of Arizona, Tucson, Arizona 85724. (An Equal Opportunity/Affirmative Action employer). (NW740)A

University of Saskatchewan CELL BIOLOGIST

Applications are invited for a position at the level of assistant professor/associate professor in either the Department of Micro-biology or the Department of Biochemistry to be sponsored by a National Cancer Institute of Canada development program for cancer re-search at the University of Saskatchewan. The program provides for sal-ary support for up to 5 years and funds for research and equipment. The appointee would be expected to work in collaboration with a multidisciplinary team who research areas include tumor metastasis, mem-brane biochemistry, chemotherapy and tumor immunology.
A PhD with at least 2-3 years post-doctoral training is required.

Applicants should send curriculum vitae, research interests, re-prints and names of three references to Dr I Ramshaw, Department of Microbiology, Univer-sity of Saskatchewan, Saska-toon, Saskatchewan S7N 0WO, Canada. (NW738)A MOLECULAR BIOLOGIST

SmithKline Corporation, a diversified multinational health care firm, located in

Philadelphia, PA, is seeking a person to develop host-vector systems for cloning and expression of eukaryotic genes. This position is located at our suburban facility, 17 miles west of Philadelphia.

The successful candidate for this new position should be capable of directing a research program on molecular genetics and become a leader in cloning and expression of eukaryotic genes. This person should have a PhD in Biological Sciences with experience in modern DNA technology as applied to one of the following areas: yeast host-vector systems, gene expression, or synthesis of cDNA.

SmithKline offers an excellent compensation program and opportunity for professional growth. Please send resume to: SMITH KLINE & FRENCH LABORATORIES, A Division Of,

SMITHKLINE CORPORATION. 1522 Spring Garden Street, Philadelphia, PA 19101. We are an equal

opportunity employer, F/H/M/V.

(NW728)A

SmithKline

British Museum (Natural History) Electron Microscopist

... to join a team involved in taxonomic research covering the whole field of natural science. Work includes preparing material for both scanning and transmission microseopy: monitoring quality and recording results; first line maintenance of microscopes and high

vacuum units and maintenance of a small

Candidates normally under 27, should have a degree in biological sciences.

Experience as a technician in an electron microscope unit would be advantageous.

For futher details and application form (to be returned by 31 July 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please auote ref: SB/68/DK.

(9016)A

UNIVERSITY OF STRATHCLYDE DEPARTMENT OF COMPUTER SCIENCE

Professor of Computer Science

Applications are invited for a second Professorship in the Department of Computer Science. To preserve the balance of interest in the Department, candidates with a knowledge either of Data Bases or the Theory of Computer Science are particularly encouraged to apply

The post will be remunerated within the professorial range for universities with USS benefits.

Application forms and further particulars (quoting 27/81) can be obtained from the Registrar, University of Strathclyde, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by 31 July 1981. (9028)A

STUDENTSHIPS

THE UNIVERSITY OF SHEFFIELD DEPARTMENT OF PHYSICS

Applications are invited for an SRC CASE STUDENTSHIP in the above department in conjunction with the British Antartic Survey. Involves studies of the Magnetosphere and Ionosphere at Halley, Antarctica, using the Sheffield ELF/VLF Goniometer and the recently installed advanced Ionosonde.

Tenable for three years during which time the recipient will analyse and interpret data acquired in Antarctica with a view to submission of a PhD thesis and publication. A good degree in Physics required.

Details from Professor T R Kaiser, Department of Physics, the University of Sheffield, The Hicks Building, Hounsfield Road, Sheffield S10 2TN, to whom applications should be sent together with the names of two referees. Quote ref: R606/G (9053)F

NOTTINGHAM UNIVERSITY

PHARMACY DEPARTMENT

RESEARCH STUDENTSHIPS The Pharmaceutics Section of the

Pharmacy Department has available SRC Research Studentships for studies on the physico-chemical properties of pharmaceutical systems and their relevance to the biological availability of drugs.

Pharmacy and Chemistry graduates interested in further details should apply to Professor S S Davis, Department of Pharmacy, University of Nottingham, University Park, Nottingham. Tel: 0602-56101 Ext (9001)F

BRISTOL **POLYTECHNIC** SCIENCE DEPARTMENT SRC RESEARCH **STUDENTSHIP**

Two SRC CASE awards have recently been approved for the following projects in the Department of Science. Duties to commence October 1981.

(1) "A study of the physiological and biochemical aspects of the development of seaweed spores" in conjunction with the Admiralty Marine Technology Establishment, Naval Dockyard Laboratories, Portsmouth.

(2) "A study of the role of ATPase enzymes in potassium transport in the midgut of caterpillars"—in conjunction with Shell Biosciences Laboratory, Sittingbourne.

Applications are invited from persons holding (or expecting to hold) a First of Upper Second Class Honours Degree in an appropriate subject. The successful candidates will be nominated to the SRC for the award of studentships. It is anticipated that the students will register for research degrees. Applications and enquiries should be sent as soon as possible to Dr T Green, Head of the Science Department, Bristol Polytechnic, Coldharbour Lane, Frenchay, Bristol BS161QY. (9022)F

STUDENTSHIPS continued

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOLOGY

SRC CASE STUDENTSHIPS

pplications are invited for two SRC ase Studentships in collaboration ith Glasshouse Crops Research stitute, Rustington, Sussex for search leading to the degree of hD. The projects are concerned ith sugar uptake by tomato fruit otoplasts and vacuoles in relation sink strength (Professor J L Hall ad Dr L C Ho) and with hormonal antrol of inflorescence development tomato (Dr D A Morris and Dr Menhenett).

Applicants should have, or expect obtain, a first or upper second class mours degree in a related subject.

Applications, including the names f two referees, should be sent as son as possible to Professor J L Hall ad/or Dr D A Morris, Department Biology, University of Southampon, Highfield, Southampton SO9 NH, from whom further particulars ay be obtained. Please quote Ref: N. (9011)F

SRC CASE STUDENTSHIP

Mössbauer studies of the Active te of Benzene Dioxygenase"

Applications are invited for an RC CASE studentship to be held in e Department of Physics in connection with the Biosciences aboratory of Shell Research Ltd. he reason, which is expected to take ree years and lead to the award of a 1D degree, will involve the pre-tration of samples of the enzyme id investigation of these samples ider a variety of conditions using ossbauer spectroscopy.

In addition to the usual SRC grant supplement of £200 pa will be paid.

Applicants should have, or expect obtain, a first or upper second class mours degree in biochemistry, bio-ysics, chemistry, physics or related hierts

Applications with a brief rriculum vitae and the names and ldresses of two referees should be nt as soon as possible to The gistrar, The University, PO Box 7, Liverpool L69 3BX, from whom rther details may be obtained. uote Ref RV/847/N (9050)F

UNIVERSITY OF

DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES

LEAF MICROCLIMATE AND THE PERFORMANCE OF FOLIAR HERBICIDES SRC 'CASE' STUDENTSHIP IN CO-OPERATION WITH

SHELL RESEARCH LTD

A studentship is available to investigate microclimatic factors which influence the action of chemicals applied to foliage of crop plants. The student who will probably have a first degree in agricultural, biological or environmental science will spend part of the time at Shell Research Laboratories, Sittingbourne, Kent. Experience in environmental measurement, or in measuring properties of leaf surfaces would be advantageous. The usual SRC studentship grant will be supplemented by £250 pa.

For further details contact Dr M H Unsworth, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough, Leics LE12 5RD. Telephone (05097) 2386. (9002)F

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF PHYSIOLOGY POST GRADUATE STUDENTSHIPS

Two SRC (CASE) post-graduate studentships are available in Neurophysiology/Neuropharmacology. The experimental work will investigate the responses of single central neurones in vivo to: a) the benzodiazepines and; b) substance P/5HT interaction on nociceptive neurones

Curriculum vitae to Dr M H T Roberts, Department of Physiology, University College, PO78, Cardiff CF11XL. (9031)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF SURGERY
BDH RESEARCH
STUDENTSHIP

A 3 year research studentship is open to candidates with a first or upper second class honours degree in Biochemistry. The value of the studentship is in line with current MRC, SERC Research Studentships. The successful candidate will form part of a multi-disciplinary research team involved in the investigation of the regulation of intermediary metabolism in the post-surgery period and the effect of postoperation metabolic support. This work will be carried out in the Surgical Metabolism Unit, Department of Surgery, University of Aberdeen, under the supervision of Dr J Broom. This unit has close ties with both the Departments of Biochemistry and Chemical Pathology, University of Aberdeen.

Applications, including the names of three referees should be made to Dr J Broom, Department of Surgery, Foresterhill, Aberdeen AB9 2ZD.

Rainbow Research Scholarship

Brewing Research

'Regulatory Mechanisms Influencing Production of Alcohols by Yeasts'

Bass Brewing Limited, in association with the University of Birmingham, invite applications for the Rainbow Research Scholarship which has been founded in memory of the contribution made to brewing science by the late Dr. C. Rainbow, D.Sc.

Applicants, male or female, must possess a first or top second class honours degree in biochemistry, microbial genetics or microbiology.

The successful candidate will spend a period of 3 years in the Research Laboratories of Bass Brewing Limited at Burton-on-Trent with short periods at the University of Birmingham. Research on the above topic will lead to submission to the University of Birmingham for the degree of Ph.D.

For the duration of the scholarship, the successful candidate will be a temporary member of the staff of Bass Brewing Limited, who will meet the costs of the project and the associated university fees.

Comprehensive applications by letter with curriculum vitae should be submitted to:

Research Manager, Bass Brewing Limited, High Street, Burton-on-Trent, Staffs. DE14 1JZ.

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES

POSTGRADUATE SCHOLARSHIP

Applications are invited from United Kingdom graduates with a 1st or II(i) Honours degree in Agricultural Science, Biology, Physiology or Zoology for a 3 year postgraduate study concerning endocrine abnormalities causing embryo mortality in cattle.

Applications, including curriculum vitae and names of two referees should be sent as soon as possible to Professor G E Lamming, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough LE12 5RD.

(9003)H

The Sports Council SPORTS SCIENCE SCHOLARSHIPS

As part of its continuing effort to improve scientific services to sport the Council is once again offering 2 Scholarships for full-time PhD research. The awards will run from October 1981, initially for 2 years, renewable for a third. The subject-matter should be in the field of medicine, physiology, biochemistry/nutritien, motor learning, or social psychology. Projects leading to practical applications are likely to receive preference.

Departments with suitable candidates are asked to submit applications specifying the research topic and the methods proposed for tackling it, the name and background of the Supervisor, and details of any minor equipment/travelling/other expenses. The candidate's full CV should be enclosed.

3 copies of the application should be sent to the Principal Research Officer, The Sports Council, 70 Brompton Road, London SW3 1EX, by July 31, 1981. (9032)H

CONFERENCES and COURSES

University of London
British Postgraduate Medical Federation

CARDIOTHORACIC INSTITUTE (In association with the Brompton Hospital)

ANNUAL PHARMACOLOGY OF ASTHMA COURSE

23rd — 27th November, 1981

This Course is of interest to scientists involved in research relating to asthma and to clinicians with an active interest in the pharmacology of asthma and the mode of action of anti-asthma drugs.

Topics to be included:

- * Leucotrienes
- * Prostaglandins
- * PAF acether
- cAMP and cell activation
- Receptor control of cell activation and receptor expression
- * Provocation testing
- Cell accumulation, Oedema, Muco-ciliary function in asthma

FEE: £150 inclusive of coffee, lunch and tea.

Places are restricted to 50. Early registration is strongly recommended.

Application forms may be obtained from: The Dean's Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP.

AMERICAN JOURNAL OF PRIMATOLOGY

Volume 1, 1981, Four Issues

The rapid growth of interdisciplinary primatology within recent years has dictated the need for an efficient domestic journal devoted to publication of high quality manuscripts spanning the entire spectrum of primatology.

The journal publishes original research reports, scholarly reviews, brief reports, and book reviews on all topics relevant to the study of primates, including all aspects of their anatomy, behavior, development, ecology, evolution, genetics, nutrition, physiology, reproduction, systematics, conservation, husbandry, and use in biomedical research. Manuscripts demonstrating a strong comparative perspective are especially welcomed.

The American Journal of Primatology is published quarterly. Should the volume of manuscripts demand it, the number of issues per year will be increased. Manuscripts are reviewed within one month of receipt and are typically published within four to eight months of final acceptance. The results of reviews, along with acceptance, suggestions for revision, or fully justified rejection, are rapidly communicated to authors. Instructions for contributors can be obtained from the editor or the publisher.

Manuscripts for consideration should be sent to: J. Erwin, Ph.D., Editor • American Journal of Primatology • P.O. Box 96 • Honeydew, CA 95545

The samples you can analyze with half a bottle of Ampholine

Cut your electrofocusing costs to a fraction of previous levels without sacrificing quality or resolution. Save substantial time casting, running, and staining gels as well. High performance electrofocusing lets you analyze well over 600 samples per bottle of Ampholine. And if you're struggling with an especially tight budget this year, we can help you save even more. High performance gels are cast by capillary action onto thin plastic support foils in layers a mere 0.5 to 0.25 mm thick. Because the new thin gels are cooled more efficiently, resolution-robbing thermal gradients are eliminated while run times drop to as little as 30 minutes.

Ampholine, the LKB tradename for the world's largest selling carrier ampholyte, is now available in four new pH ranges. The new ranges are specially preblended for direct use in either acrylamide or our new agarose gels and exhibit excellent conductivity and reproducibility. By switching

to our new preblends, you'll save preparation time and reduce your stocking costs as well.

High performance electrofocusing is just one of a series of new and improved techniques you can perform on the Multiphor * System. For more details about this and other new kits soon to be released, contact your local LKB representative. We have offices everywhere. Or phone us today at one of the addresses listed below.

Aims and Scope

Toxicology is the study of the adverse reactions of living creatures to noxious influences. This is a scientific discipline. What matters to man are the hazards to which he is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life. This is the subject of Human Toxicology, for which this journal caters. It embraces both animal research, which has direct significance for man, and studies with humans in their own right — biochemically, physiologically, clinically and epidemiologically.

Main Features

The following material will appear on a regular basis:

- Original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans
- Short communications and comments on current matters of professional interest
- Editorials on topical issues
- Reviews by invited contributors on important aspects
- Authoritative book reviews

Call for Papers

The submission of suitable papers for editorial consideration is welcomed. Papers must be in English and two copies should be submitted. References, collected at the end of the paper, should include the author's name, year of publication, title of article, title of publication, volume number and first and last page numbers. They should be listed in alphabetical order. A detailed list of *Instructions to Authors* can be obtained from the Publisher. Papers should be sent directly to the Editorial Secretary. Human Toxicology, 4 Little Essex Street, London WC2R 3LF England, or to Human Toxicology, Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

PUBLISHERS

From DNA to RNA and beyond

These nine systems represent a major achievement in support of DNA/RNA research. They offer pretested, quality-assured sets of matched ingredients for analyzing genes and the products of their expression.

and the second of the second o

You could of course assemble the ingredients yourself, but here's what you'd likely be missing: Reliability, reproducibility, and hours of time better spent doing the research.

Call to discuss any questions you may have for our technical staff.

Nick Translation

Two exclusive systems for making consistently high specific activity probes using nick translation: dCTP, [32P]- and dTTP, [3H]-. Both systems include *E. coli* DNA Polymerase I prepared in our laboratories to ensure reproducibility. The DNase I, dNTP mixtures, stop buffer, and sterile deionized water are optimized for compatibility and stability.

Systems sufficient for either 20 or 10 reactions contain the following:

dCTP, $[\alpha^{-32}P]$ -, or

dTTP, [methyl, 1', 2',-3H]-

DNase I

DNA Polymerase I

Control Plasmid DNA (pBR322)

Deoxynucleoside Triphosphate

Mixture

Nick Translation Buffer Nick Translation Stop Buffer

Deionized Water

Each lot of systems is tested with the control supercoil pBR322 plasmid DNA to ensure efficient incorporation of dCMP or dTMP into DNA, and a copy of the curve is included with your system.

Ordering information:

NEK -004 (dCTP, [α-32P]) (20 reactions, tracer in ethanol) NEK-004A (10 reactions, tracer in ethanol) NEK-004B (20 reactions, tracer concentrated in aqueous solution) NEK-004C (10 reactions, tracer concentrated in agueous solution) NÉK-005 (dTTP, [3H]) (20-reaction system)

3' End Labeling

The system labels protruding (Hae II), flush (Alu I), and recessed (Hinf I) 3' termini generated from pBR322 with 3'-dATP, $[\alpha^{-32}P]$ - (cordycepin 5'-triphosphate) in a simplified protocol similar to the procedures of Tu and Cohen. 1 The system utilizes terminal transferase to add a single 3'-dAMP, $[\alpha$ - 32 P]-molecule to the 3end of a DNA chain. The resulting labeled DNA is suitable for sequencing by the Maxam and Gilbert2 technique used in our new DNA Sequencing System (see next page).

The components include:

3'-dATP, $[\alpha$ -32P]- (cordycepin

5'-triphosphate)

Terminal Deoxynucleotidyl

Transferase

Terminal Transferase Reaction

Buffer

Cobalt Chloride

Control Plasmid DNA Fragments

Deionized Water

Prior to shipment, all system components are subjected to a complete 3' end labeling procedure. The polyacrylamide gel used to separate the fragments is autoradiographed to assess labeling efficiency, and a copy of the autoradiogram is included with your system.

Ordering information:

NEK-009 (10-reaction system) NEK-009A (5-reaction system)

Tu, C.-P.D. and Cohen, S.N., Gene, 10: 177, 1980

5' End Labeling

Adapted from procedures describ by Maxam and Gilbert,2 an efficien time-saving means of labeling nucleic acid fragments preparato to DNA sequencing (see next column). The system includes ATP, $[\gamma^{-32}P]$ - with polynucleotide kinase prepared in our own laboratories, and a carefully balanced complement of buffers, enzymes, and other reagents necessary for labe ing the 5' termini of DNA fragmen

Systems sufficient for either 10 or reactions contain the following:

ATP, $[\gamma^{-32}P]$

Alkaline Phosphatase

Polynucleotide Kinase (purified to

homogeneity)

Phosphatase Buffer

Direct Phosphorylation Buffer Exchange Phosphorylation Buffe

Hinf I Digest of Plasmid DNA, pBR322 (control to check system

Deionized Water

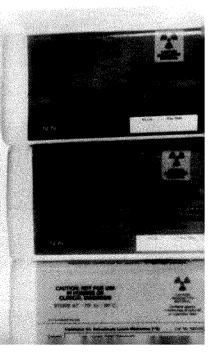

The system is tested the day befor

✓ shipment using the same lots of components you will receive, including fresh tracer. The resulting autoradiogram is included with your system.

clusion with the system.

axam, A.M. and Gilbert, W., Methods in zymology, 65 (1980)

NEW Transcription

This system provides all the components necessary to perform eukaryotic cell-free transcription. It contains a cell-free extract derived from HeLa cells which catalyzes the synthesis of mRNA precursors when provided with an exogenous DNA containing a promoter for recognition by the polymerase. This RNA polymerase II dependent reaction is highly sensitive to the presence of α -amanitin. The whole cell extract is prepared as described by Manley and coworkers. 3

The system also includes UTP, $[\alpha^{-32}P]$ - for labeling specific mRNA precursors. A control DNA template, the cloned Bal I-E restriction fragment of Adenovirus-2, has been used to optimize the system and is included with it. This control should be used by the investigator to determine proper functioning of the system.

Components sufficient for performing 50 assays (25µl reaction volume) are listed below:

UTP, $[\alpha^{-32}P]$ HeLa Cell Extract
Control DNA Template
Transcription Cocktail
Deionized Water

Ordering information: NEK-014 (50-reaction system)

Translation

Now Proline [3H]

NEN's *in vitro* protein translation systems have made cell-free translations of eukaryotic mRNAs exceptionally reliable and reproducible. These systems are offered with either Methionine, L-[35S]- or Leucine, L-[3H]- or Proline, L-[3H]- labeled tracers. All three utilize an extract of rabbit reticulocyte lysate that has been treated with micrococcal nuclease to remove endogenous mRNA. The lysate is prepared under strictly controlled conditions to ensure retention of high protein synthesis activity.

The components include:
Rabbit Reticulocyte Lysate
Methionine, L-[35S]-, or
Leucine, L-[3,4,5-3H]-, or
Proline, L-[2,3,4,5-3H]Translation Cocktail
Control mRNA
Magnesium Acetate
Potassium Acetate
Deionized Water

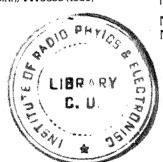

Each lot of systems is biologically tested with the control mRNA. A graph demonstrating Methionine, Leucine, or Proline incorporation is provided with your shipment.

Ordering information:

NEK-001 (Met [35S]) (100 reactions) NEK-001A (incl. extra ml lysate) NEK-001B (tracer shipped as needed)

NEK-002 (Leu [3H]) (100 reactions) NEK-002A (incl. extra ml lysate)

NEK-013 (Pro [°H]) (20 reactions) NEK-013A (100 reactions)

Available only from BRL

C-5 ANALOG

for Nucleic Acid Chromatography

After extensive research, development, and testing, BRL is now introducing RPC-5 ANALOG, a chromatography matrix with performance properties quite similar to the well-characterized RPC-5.1 RPC-5 ANALOG chromatography is a useful tool for analytical and preparative fractionation of:

- Bacterial plasmids and supercoiled viral DNA
- Cloned DNA fragments
- **DNA restriction fragments**
- Oligomers of ss-DNA and RNA (synthetic and natural)
- Complementary strands of restriction fragments
- Recovery of DNA from agarose gels

Wells, R. D., Hardles, S. C., Horn, G. T., Klein, B., Larson, J. E., Neuendorf, S. K., Panayotatos, N., Patlent, R. K. and Seising, E. (1980) Methods in Enzymol. 65, 372-347.

The performance characteristics of RPC-5 ANALOG make it the resin of choice for molecular biologists interested in nucleic acid chromatography because it provides:

- High resolution
- High capacity
- Quantitative recoveries (milligram quantities)
- Rapid separations
- Reduced costs
- Ease of use

for DNA Plasmid Purification

RPC-5 ANALOG column chromatography is especially useful in the purification of plasmids from cellular lysates as illustrated in Figure 1. The resolution of the plasmid is so complete that BRL has been able to develop a rapid batch method that still yields plasmids of 99% purity (Table I).

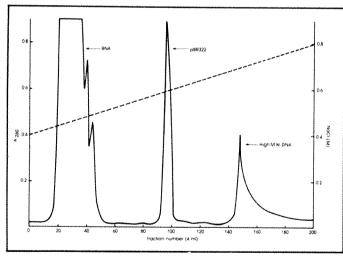

Figure 1. RPC-5 ANALOG chromatography of a total nucleic acid extract of a (pBR322). The nucleic acids were added to the column in 0.2 M NaCl, 10 mM Tris-HCl (pH 7.2) and 10 mM EDTA and eluted with an increasing linear salt gradient (0.4 - 0.8 M NaCl).

How Britain runs its Science

This highly successful wallchart, which first appeared in 1975, has now been completely revised and updated.

The 2×3 ft guide offers a comprehensive survey of the administration of British science. It provides a full account of the funding of science in Britain, giving details of money spent by government, research councils, industry and universities.

Designed as a fold-out sheet, it can be carried easily to meetings or hung as a wall poster for permanent reference. The new 1981 edition is available at £3.50 or \$7.95 by sending your cheque to either Nature's London or New York offices.

In the UK and elsewhere: Nature, 4 Little Essex Street, London WC2R 3LF, England.

In the US and Canada: Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). A draft abstract (50 words) is required.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature.

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be appreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

MICRO 82 international symposia & exhibition

at the Bloomsbury Centre Hotel Coram Street, London WC1 12-16 July 1982

CONFERENCE includes the following Topics:-

Developments in Electron Optics (TEM and SEM) Autoradiography Symposium and Workshop Cytodifferentiation - Nuclear and Plant High Resolution Electron Microscopy SEM/TEM Biological and Medical Applications Sample Preparation Workshop Microscopy in the Medical and in the Industrial Laboratory Microscopy of Food Microscopy of the Degradation of Materials -Oxidation, Corrosion, Fatigue, Erosion and Wear Latest Developments in Cytometry Immunocytochemistry Immunohistochemistry of Lymphomas Histochemistry of Differentiation Safety in the Microscope Laboratory Microscopy in the Classroom

EXHIBITION (in association with NATURE) will be open as follows :-

MONDAY	12 July	1230 - 1830
TUESDAY	13 July	0930 - 1830
WEDNESDAY	14 July	0930 - 1830
THURSDAY	15 July	0930 - 1830
FRIDAY	16 July	0930 - 1300

Nuclear issues in the Middle East

The conclusion that the Israeli raid on the Iraqi reactor at Tamuz on 7 June will have caused more diplomatic than physical damage is strengthened as the weeks pass. The organization now most on the defensive is not the government of Israel but the International Atomic Energy Agency in Vienna, which has had the invidious task in the past month of defending itself against the charge that its technical safeguards intended to prevent the diversion of fissile materials to military purposes are inadequate to the need. At the same time, many readers have taken offence at the leading article of 18 June which, among other things, argued that the Israeli attack was unjustifiable and that steps should now be taken, chiefly by the United States, to ensure that Israel signs the Non-Proliferation Treaty. The letters of protest have several themes in common — that the Tamuz raid was not a breach of international law because Iraq and Israel are technically in a state of war; that Iraq's motive for embarking on a nuclear programme cannot have been pacific, given its substantial reserves of petroleum; that Iraq's membership of the Non-Proliferation Treaty is irrelevant because the safeguards procedures are ineffective; and that in any case it is no business of a journal such as Nature to discuss political questions such as those prompted by the raid on Tamuz.

The real world, unfortunately, is neither as tidy nor as simple as these protests imply. Those who complain that a scientific journal has no place in politics are in general correct. It would, for example, be inappropriate (and deeply offensive to the bulk of readers) if a journal such as this were to take sides in a political election, "endorsing" this or that candidate for, say, the United States presidency (which is not, of course, to say that candidates' election promises about support for research are of no interest). There are, however, exceptions to the general rule. To the extent that complaints about the British government's policy on the universities chime in with those of the government's political opponents, they are inescapably political. And there is hardly any aspect of the Non-Proliferation Treaty, a matter of inescapable interest to the scientific community, that is strictly technical. The treaty, founded on the bargain between non-nuclear and nuclear states that the former would refrain from making weapons and that the latter would help with the development of civil nuclear technology, is intrinsically as much political as technical. More generally, it has been plain since the early 1960s that the widespread wish to inhibit the spread of nuclear weapons cannot be attained by strictly technical means; as the environmentalists used to say, there is no technological fix. Neither the treaty nor the safeguards elaborated since it came into force eleven years ago are a cast-iron assurance that weapons will not spread. International pressure and the fear of strategic countermeasures are essential ingredients in the now elaborate but untidy system of restraints that has developed. Those who consider that the reality is different should ask themselves why the first Indian nuclear explosion has not been followed by a second even after the passage of seven years.

But why should the scientific community have an interest in arrangements for inhibiting the spread of nuclear weapons? To quote J.R. Oppenheimer's remark at Alamogordo in 1946 that "the physicists have known guilt" would be to over-dramatize the case. Rather, the development of nuclear energy is the most striking illustration so far that research and development is rarely a benefit unalloyed. For the past three decades, the scientific community has been the chief source of policies for the sensible control of nuclear energy, both domestically and internationally.

Individual scientists have had a decisive influence on diplomatic innovations whose effect is to inhibit the spread of nuclear weapons. Thus the Partial Test-Ban Treaty is more a monument to Dr Jerome Wiesner's flair and persistence than to the good sense of his colleagues in the White House in the early 1960s. The safeguards system now operated by the International Atomic Energy Agency, although imperfect, is one of many illustrations that technical devices (and people) can serve wider interests. But to suppose that in such matters technical people should be inarticulate servants of the diplomats is not merely to ask too much of flesh and blood but to ignore the constructiveness of what the technical community has to offer. As it happens, the present is a time of exceptional anxiety about the future development and deployment of nuclear weapons. Can it seriously be suggested that technical people should help to work out and implement agreements of the kind for which people like Chancellor Helmut Schmidt have been asking for the past several months in strict innocence of the underlying issues? That may be a more substantial dereliction of responsibility.

So what are the issues provoked by the raid on Tamuz? The efficacy of the international agency's safeguards systems is certainly one of them. And it is proper openly to acknowledge that the safeguards system is not leak-proof. It never has been and never could be, which is why those who now pretend that the raid on Tamuz has for the first time revealed the truth are guilty of disingenuousness. For the system depends on the collaboration of national governments, which must disclose their activities in nuclear energy (and which could, in theory, keep some hidden). It supposes that inspections of, say, a reactor will reveal all, when some parts of all nuclear installations must be inaccessible on safety grounds. It relies to some extent for the detection of violations on the accumulation of information about a nuclear installation over a period of time, while on paper the treaty permits the resignation of any member state on three months' notice. It requires (but unnecessarily) that inspectors should keep the information they gather confidential, although the appearance of Dr Roger Richter before the Senate Foreign Relations Committee in Washington three weeks ago on the introduction of Senator Alan Cranston (who is not, as erroneously described last week, the chairman but only a member of the committee) shows that even that stipulation can be circunvented.

But so what? The Non-Proliferation Treaty is not the only treaty of its kind that relies on less than perfect arrangements for the detection of violations. Who, for example, would pretend that the requirements of the Threshold Test-Ban Treaty (which restricts the yield of underground nuclear tests to the equivalent of less than 150,000 tonnes of TNT but which relies on seismic measurements of actual yield that may be in error by a factor of two) are cast-iron? For at least two decades it has been accepted that no arms control treaty can embody cast-iron arrangements for verification. The objective is to ensure that the risk of detection is great enough to deter violation - and that the diplomatic risks of abrogation are equally forbidding. It was irresponsible of Senator Cranston to pretend that Dr Richter's evidence amounted to the first discovery of these truths, just as it was reprehensible of Dr Richter to give the Foreign Relations Committee a partial account of the internal discussions of the Iraqi reactor within the international agency. (Dr Hans Gruemm's account on page 187 is inherently more credible.)

Two other issues have been raised by correspondents, of which

0028-0836/81/290185-02\$01.00

the argument that the raid on Tamuz was legal because Israel and Iraq have never signed a peace treaty with each other is the least substantial. The delicacy of the military and political problems of the Middle East is notorious and several states, supporters of Israeli independence prominent among them, have spent much of their energy in recent years (no doubt partly from self-interest) seeking devices (of which Israel has known and approved) for making life less dangerous for Israelis and Iraqis. Mrs Jeanne Kirkpatrick, the United States representative at the United Nations, told the Security Council on 19 June that Israel had "hurt, not helped, the peace and security of the area". The same meeting of the council went on unanimously to adopt a resolution condemning the Israeli raid on Tamuz, asserting that Iraq should be compensated and demanding that Israel's nuclear facilities should be subject to international safeguards. Legality does not often excite such strictures.

What, then, happens next? The new government of France, which originally agreed to the contract under which the reactors at Tamuz were built, has fortunately reafffirmed its curious quasiadherence to the Non-Proliferation Treaty - although not a signatory itself, it requires its nuclear customers to sign. Indeed, President Mitterrand, no doubt in reaction to recent bellicosity about nuclear weapons by President Hussein of Iraq, has made plain his intention of being even tougher in the future. In the United States, there is also now a prospect of a more rational antiproliferation policy — the new Administration is apparently to announce this week its acceptance of the explicit bargain in the treaty that nuclear powers must be dependable sources of nuclear technology and materials if non-nuclear powers are to continue with their undertaking not to make nuclear weapons. (The promise does not distinguish between states with and without reserves of petroleum, nor should it.) There is much that could be done to improve the safeguards procedures of the international agency, but to the extent that non-nuclear powers may be required to assume obligations not originally contracted for, these questions should be raised at the next review conference of the treaty four years from now (which, as these things go, is almost tomorrow). Some attention should also be paid to recent Israeli advocacy of a nuclear-free zone in the Middle East - the stumbling block so far is that such a treaty would entail recognition of the state of Israel by its Arab neighbours and thus a resolution of the whole problem of the Middle East, but that is not a sufficient reason for ignoring the subject. The most immediate need, however, is that the nuclear powers and especially the United States should give whatever help they can to the international agency that has the invidious task of supervising the working of the Non-Proliferation Treaty. Behaving as if the treaty means what it says, which it does, is the most urgent need. Beyond that, it is essential that the nuclear powers signatory to the treaty should recall the reasons why they were given a drubbing at the second review conference in August last year, and that they should do what they can to implement those provisions of the Non-Proliferation Treaty that promise further steps (beyond Salt I) towards strategic arms control. Is it possible that Mr Eugene Rostow, now confirmed as director of the United States Arms Control and Disarmament Agency and a hawk in President Kennedy's administration, will be a dove in Mr Reagan's?

Lightning without cause

The British university system, more than ever alive with rumour when it is not already on vacation, is buzzing with a curious canard; is it possible, people are asking, that the way in which the cuts announced last week by the University Grants Committee have fallen has been surreptitiously guided, even invited, by stoolpigeons within the institutions concerned? This fanciful notion seems in many places to be the simplest explanation of how, without apparent consultation, the University Grants Committee has been uncannily perceptive in its suggestions of how individual universities should trim their sails. A university whose members have for years been complaining among themselves that too many

biological departments teach their own individual introductory courses is likely now to have been told to cut back on the teaching of "conventional biology". Chemistry departments here and there, whose members from time to time hang their heads with shame about the quality of their collective research, have found that their universities (against the general trend) have been advised to cut back on physical science. But who can have spilled the beans about this supposedly secret knowledge? Academics are understandably looking with suspicion at their vice-chancellors, those people who travel most often to London.

The truth is simpler. Supposedly secret knowledge is usually not as secret as its holders suppose. Many of the grants committee's negative decisions - "cut this, cut that" intelligible. For more than a year, for example, the committee has been urging that too many British universities have been making too much provision for the teaching of Russian; is it surprising that Russian departments were conspicuous among those marked out for oblivion two weeks ago? It is a misfortune that so few would-be students at British universities seek to be Russian experts. The grants committee's recommendations in other fields, and in the sciences especially, are harder to understand. Although some of the universities now complaining that they have been told to close departments superficially in the national interest know secretly that their case is only weak, others are genuinely (and rightly) puzzled. At least part of the explanation seems to be that the grants committee has relied on the public research councils for advice on the health and strength of research in departments of this or that at particular universities, discounting the importance of industrial support. But even more machiavellian calculations may have been involved; is it possible that the committee has assumed that the universities most seriously affected by its cuts are few enough in number to be able to capture support from industry? If so, the calculation is in error. Industrial companies will seek to back the winners in the committee's sweepstake, not the losers. And the chance of forcing a few British universities to make a new (and industrially-linked) way for themselves has been lost.

Science and technology in the new pattern of British universities will also be affected by a previously unremarked feature of the grants committee's general letter to universities the absence (for the first time for many years) of "advice" about the way in which total student numbers should be partitioned between undergraduates and graduate students. Briefly, it will be left to universities individually to decide what balance should be struck. Those universities most seriously deprived of funds will decide, other things being equal as the economists say, to take in more undergraduates and fewer graduate students (who are more expensive). This simple calculation will, however, be muddled by calculations of the costs of dispensing with tenured faculty members. In the interests of the British university system, it would be a great advantage that postgraduate education should be more concentrated than it is, but it is unreasonable that universities that would benefit from following such a course should be expected to do so if the immediate consequence is that there is even less to spend on immediate needs — and no mechanism for making sure that bright undergraduates have a means of becoming graduate students themselves.

What this implies is that the grants committee's declarations about the immediate prospects for British universities cannot in themselves become a policy for the universities. They are at best a challenge to the other interested parties — the research councils, the universities themselves but also the government — to hammer out some kind of policy for the future. On present form, and that of the past two weeks, nothing much will happen. Most of those most closely concerned will be on vacation between now and when the cuts begin to bite. By then, it will be apparent that it is too late even for invigorated administrators of the British university system to exert much influence. The danger, as things have turned out, is that the academics most threatened by what the grants committee has decreed will be on holiday when crucial decisions must be made about the institutions for which they work. Too bad, people will be saying.

Row over nuclear safeguards continues

IAEA official denies evidence to Congress

The evidence given by Dr Roger Richter in the past few weeks to the foreign relations committees of the United States Congress was distorted, partly for effect and partly out of ignorance, according to Dr Hans Gruemm, the Austrian physicist who is head of the safeguards division of the International Atomic Energy Agency (IAEA). Dr Gruemm was speaking at a conference of the Institute of Nuclear Materials Handling in San Francisco on Monday this week.

In his address, Dr Gruemm acknowledged that the attack on the Iraqi reactor at Tamuz on 7 June, and the public comment that had followed — as well as Dr Richter's removal of confidential papers from the agency — had undermined the credibility of the safeguards system. He said, however, that the agency's internal memorandum dated 10 March, made public during the Senate hearings, was only one of several documents circulating within the agency and concerned with the improvement of safeguards on large research reactors.

The memorandum of 10 March, addressed to Dr Gruemm by Dr T. Shea of the agency's safeguards division, is a minute of a staff meeting on 12 February called to consider the feasibility of closing two loopholes in the agency's safeguards procedures — the possibility that a state covered by inspection might not have declared all the nuclear material used in its operations, and the possibility that reactors under safeguards might be used for making plutonium (or uranium-233) by the clandestine irradiation of natural uranium (or of thorium).

The meeting concluded that it would not be feasible to detect undeclared stocks of nuclear materials except by means of country-wide surveillance not covered by the safeguards provisions. On the use of reactors for the production of fissile material by neutron bombardment, the meeting apparently acknowledged that routine inspection would not always detect the use of uranium or thorium in this way because of the frequency with which samples for irradiation would normally be loaded and withdrawn (as in the production of short-lived isotopes), listed five technical devices that might serve continuously to monitor such illicit uses, agreed that none had been "identified" as "effective and efficient" and suggested further study. Dr Richter, in his account of these proceedings, did not say that the

agency was concerned.

Dr Gruemm said in San Francisco this week that the meeting in Vienna in February (at which Dr Richter had not been present) was only one of several technical meetings called to discuss improvements of safeguards procedures made possible by the recruitment of extra inspectors. He complained that Richter had not mentioned that studies of the feasibility of detecting the use of research reactors for manufacturing fissile material had been begun in 1980.

Dr Gruemm also said that detailed studies of the Tamuz reactor as a means of producing clandestine fissile material were begun at the end of 1979, when the agency was first informed of the transfer of natural and depleted uranium to Iraq. The agency's calculations showed that it might be possible to produce between one and two "significant quantitics" (bomb units) of fissile material each year, but that this would be possible only by replenishing the

reactor core "several times a year" with enriched uranium, presumably from France. To make optimum clandestine use of the reactor, it would also have been necessary to add cooling circuits to the reactor, which would have been visible on inspection.

Dr Gruemm's statement in San Francisco is, however, unlikely soon to still the argument about the efficacy of the agency's safeguards, even though the agency appears to have resolved its previously chronic manpower problems—its professional safeguards staff increased fourfold (to 206) between 1970 and 1980.

Meanwhile, interest in the capacity of Israel to manufacture nuclear weapons has been revived by the report of a panel appointed by the United Nations, including Dr George Quester of Cornell University as its United States representative, that Israel is probably now in a position quickly to produce a substantial number of nuclear weapons.

Chevènement still battling for control

The nouvelle politique of science in France is off to a shaky start. Jean-Pierre Chevènement, Minister of State for Science and Technology, is still struggling with the Ministry of Industry for the control of certain key institutions; while on the other wing the more radical unions are calling for the resignation of certain research directors of the old regime.

The minister's contribution, announced last week, to the new 1981 budget — an adjustment to that of the previous government's — also falls a long way short of what he must aim for to bring French research and development spending up to the promised 2.5 per cent of gross national product by 1985. He will ask the National Assembly for an additional FF 154.9 million (around £15 million) compared with a total 1980 expenditure of FF 14,500 million, excluding defence research. That amounts to a 1 per cent increase; M. Chevènement will need ten times as much next year

Of this year's extras, the minister will ask for FF 68.5 million to pay new salaries at the Centre National de la Recherche Scientifique (CNRS) — the main basic research agency - and at the Institut National de la Recherche Agronomique. Chevenement foresees the creation of 525 new posts, most of them for technicians and administrators. Then FF 25 million would prop up the contribution to the European centre for nuclear research (CERN) against the recent fall in the French franc. And FF 61.4 million would increase running budgets — but not of the basic research agencies. The Agence Nationale pour la Valorisation de la Recherche, which helps to convert discoveries in French laboratories into

innovations in French industry — and is rather a pet of M. Chewenement's — would get FF 60 million, and the remaining FF 1.4 million would go to the Centre National pour l'Exploitation des Océans to create fish farms.

Meanwhile Chevènement is struggling to establish his authority over the nonmilitary research activities of the atomic energy and space authorities (CEA and CNES), and of the Agence Nationale pour la Valorisation de la Recherche itself, all of which at present belong to the Ministry for Industry. Chevènement's determination to control these agencies, in one way or another, and so to have - through the management of innovation — a major say in the socialist transformation of French industry, is not going down well among industry ministry bureaucrats, and they are now briefing their second minister in a few months, M. Pierre Dreyfus, to resist the scientific upstart.

However, Chevenement will almost certainly gain control of the Centre National de la Recherche Scientifique. where the unions - to whose interests Chevènement is sensitive — are becoming active. Most dramatically, the communistaffiliated Syndical National des Chercheurs Scientifique last week called for the resignation of both the president and director of CNRS, Professor Charles Thibault and M. Jacques Ducuing. The director-general of the medical research agency, INSERM, M. Philippe Laudat, should also resign, said the union. They stand in the way of progress, according to the union secretary-general M. Michel Gruselle. Chevènement is cryptic; when asked recently if heads would roll, he said "we shall see". Robert Walgate

Fusion research

Where to next?

Brussels

The European Economic Community and its partner countries, Sweden and Switzerland, should go ahead with research into thermonuclear fusion — according to the European fusion review panel. The road to commercial fusion will, however, "be long and costly" and it appears unlikely that commercial fusion power will be in general use within the next 50 years. These are the main conclusions in the review panel's report published last week.

The European Commission has also released the proposed programme for the next five years (1982–86) which will now be discussed in the committee of the member states' permanent representatives (Coreper). It says that a major landmark in fusion research has almost been reached. There is a good prospect that the full objectives of JET (Joint European Torus) may be achieved and that the results could go beyond the stated objectives and attain thermonuclear ignition.

The construction of the basic JET device is now expected to be completed by the end of 1982 and the first discharge could take place in April 1983. A problem in going further, the review panel's report points out, is that the device will become radioactive and hence inaccessible after experiments with tritium take place. But unless this step is taken, JET cannot be used to answer the crucial question of how the plasma behaves when alpha particles from the deuterium-tritium reaction are produced in large quantities. This knowledge is essential for progress towards the stage after JET.

This next step is called, with refreshing logic, NET (Next European Torus) and would demonstrate the technical feasibility of a commercial tokamak. The concept of an international commercial demonstration tokamak (INTOR) is being studied under the auspices of the International Atomic Energy Authority (IAEA). The review panel recommends that the Europeans need to make preparations for studies of the newtechnologies.

"But the Community will only be able to contribute to and benefit from INTOR if it develops in parallel its own design of a next step device and the technological know-how necessary to undertake its construction. Both the Japanese and Americans are planning their own next step devices" warns the report.

The panel also weighs up the pros and cons of fusion research apart from the tokamaks and, not surprisingly at this early stage in the art, feels that options should be kept as wide open as possible. The three new specialized tokamak projects (TORE SUPRA, FTU, ASKEX-UPGRADE), which are at various stages of design, are also considered well justified.

Both the European Commission and the review panel favour the Reverse Field Experiment (RFX) proposed by laboratories in Culham, Padua and Los Alamos. An agreement has been drawn up under which the United States contributes \$8 million out of the total cost of \$48 million, but this awaits approval from the member states. The United States is also likely to participate in the two-stage development of the Advanced Stellarator. This would mean rebuilding the existing device in Garching, West Germany, and a new and much bigger stellarator later on.

All this research is likely to cost around 1,500 million European Units of Account (£740 million) over the next five years, according to the report: 400 million for JET, 560 million for the running costs of the associated laboratories, 125 million for investments in new supporting tokamaks, 260 million for the technology programme and NET and about 40 million for investments in the new alternative devices. This agrees with what the Commission has outlined.

The review panel's report highlights several issues likely to give rise to political problems. One of these is the future of Culham. Should it be the site of the next step project and what should be done to prevent the tokamak becoming useless once it is radioactive? Also questioned is the belief that fusion is as unpolluting as has been argued - the radioactive waste will have to be stored. Finally, there is a danger that the duration of nuclear fusion research will outstrip the mortality of its acolytes. The average age of Community staff is 45 and the increase of average age is very nearly one year per year. Thus in about 15 years time when these staff retire, most of the know-how acquired in 30 to 40 years of research "will disappear rather Jasper Becker suddenly.'

Clinch River reactor

Start again folks

Washington

After four years of delay caused largely by President Carter's reluctance to make a full-scale commitment to the "plutonium economy", plans for the construction of a liquid metal fast breeder reactor at Clinch River in Tennessee have been put squarely back on the rails by the US Congress.

Despite support from President Reagan, it was never a foregone conclusion. In May, the Science and Technology Committee of the House of Representatives voted against funds for the initial construction work on the 350 megawatt reactor, which has been on the drawing board since the early 1970s, and for which over \$500 million worth of components have already been delivered.

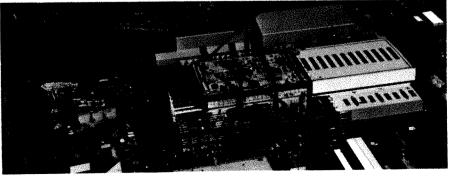

In previous years the same committee had spearheaded congressional efforts which succeeded in preventing President Carter from killing the project; this time, cost-conscious Republicans added their voices to the previous minority which had argued that no further federal funds should be committed.

But larger political forces were at work. In particular, strong support for the construction of the Clinch River reactor came from Senate Leader Howard Baker, who represents Tennessee, and for whom the reactor means both jobs and votes. Reflecting Mr Baker's wishes, the House accepted a Republican amendment to the budget bill at the end of last month which overturned the recommendations of the Science and Technology Committee and inserted \$230 million for preliminary construction of the reactor as proposed by Mr Reagan.

Similar approval has already been given by the Senate (which, ironically, has in past years voted to terminate the project). And although the decision to go ahead with construction must now pass through the appropriations process, it seems that after the crucial House vote this will be little more than a formality.

Opponents of the fast breeder maintain their opposition on several grounds. One is that the declining price of uranium over the past three years has reduced the need for a rapid breeder programme. The pressure has also been eased by declining predictions of future demand for electricity. And even many of those who support fast breeders in principle feel that the Clinch River design is now out-of-date.

The critics appear to have a covert ally in the new director of the Office of Management and Budget, Mr David Stockman. Long opposed to heavy federal subsidies for energy demonstration projects, Mr Stockman wrote to fellow Congressmen in 1977 stating explicitly that the federal government's 90 per cent support for the Clinch River reactor was "totally incompatible with our free-market approach to energy policy".

JET nears completion

Yet with over \$100 million of their own money already spent, the 733 utilities involved have been pushing for construction to go ahead. The level of jingoism has been high. Visitors to the Clinch River site are given a free coffee mug inscribed "we are fighting for energy independence". And in a letter expressing their support, 17 members of a group known as Scientists and Engineers for Secure Energy, headed by ex-president of the National Academy of Sciences, Frederick Seitz, gave as one of their reasons that "in view of recent political developments in certain Western countries, particularly France, the Clinch River Project may become the only reliable technological undertaking of its kind in the free world".

But in the end the personal support of Senator Howard Baker has been decisive. As characterized in the House budget bill, the liquid metal fast breeder reactor (LMFBR) will be one of a series of steps designed to bring US breeder technology in line with that of other industrialized nations.

The most recent of these steps has been the successful operation last December of the Fast Flux Test Facility (FFTF) at the Department of Energy's Hanford Reservation in Washington State. Late in March of this year, the 400 megawatt test facility emerged with flying colours from a safety test in which the reactor was shut down from full power, and the main coolant-circulating pumps were turned off. Construction of the Clinch River reactor, say its supporters, is the logical next step.

In approving the Clinch River funding (and therefore channelling support away from solar energy and conservation research which the Science and Technology Committee in the House of Representatives had preferred), the House authorized an initial \$15 million for the planning of a 1,000 megawatt reactor.

How much future support for the breeder programme will, in fact, be forth-coming from the Reagan Administration remains uncertain. In his formal presentations, budget director David Stockman has forsworn his earlier statements and repeated the Administration's support for LMFBR. In private, however, Mr Stockman and his officials at the Office of Management and Budget are said to be strongly opposed to further substantial government subsidies of the nuclear industry, including its fast breeder plans, preferring that the utilities should pay.

Meanwhile opponents have not given up the fight. They are giving wide publicity to the findings of a congressional investigation team that some of the contractors may have been overcharging for components already supplied. In the wings is a debate about whether the reactor meets the new siting requirements introduced by the Nuclear Regulatory Commission after the Three Mile Island accident. Congress may have made up its mind, but the public debate is far from over.

David Dickson

Research ethics and safety

Changing the guard

Washington

In a small but symbolic way, last Thursday may turn out to be a significant turning-point in the history of public controls on genetic engineering. Meeting in Bethesda, Maryland, an advisory committee to the National Institutes of Health (NIH) decided to recommend to its parent body, the Recombinant DNA Advisory Committee (RAC), a further substantial relaxation of the safety controls applied to recombinant DNA research.

Meanwhile 50 miles away, in the depths of the Virginia countryside, a presidential commission established to look at the ethical problems raised by biomedical advances has suggested the establishment of a new body — possibly at an international level — charged to seek a social consensus on the various dilemmas which the expanding clinical use of genetic engineering techniques will raise.

The RAC subcommittee was set up at a meeting of the full committee in May to discuss proposals for a significant relaxation in the safety guidelines made by Dr David Baltimore of the Massachusetts Institute of Technology and Dr Allan Campbell of Stanford University (Nature 7 May, p.3).

The subcommittee, whose recommendations will now be discussed at the next full meeting of RAC in September, did not agree that NIH guidelines should be made voluntary. However, they did suggest that detailed rules for the composition of local institutional biohazards committees (IBC) be removed.

If eventually approved by NIH, this would mean that research institutions would no longer be required to include "public interest" representatives, for example, on their IBC (although many would probably continue to do so). It could also mean that the responsibilities of the IBC to ensure compliance with the guidelines could be delegated to a single institutional biosafety officer.

The subcommittee also supported a proposal to eliminate from the guidelines a detailed listing of containment procedures, and its replacement by a statement that such procedures should follow recommendations being developed by the Center for Disease Control for experiments using the host or the vector separately.

In other cases the subcommittee proposed that P1 containment levels be used, and that a statement be included about donor DNA, saying that if there is clear evidence that the donor DNA will significantly alter the pathogenicity of the host, then the appropriate containment level will be applied.

Some of the suggestions approved by the subcommittee — for example that all prohibitions requiring special permission from the director of NIH, including work with

Ziman speaks out

Professor John Ziman on Monday strongly criticized the Royal Society, of which he is a fellow, for sluggishness on human rights issues. He was addressing the All-Party Parliamentary Committee for Soviety Jewry at a special award ceremony in the House of Commons, at which he received on behalf of Dr Viktor Brailovskii, who last month was sentenced to five years' Siberian exile, a Henry Moore lithograph entitled "for courage in defence of freedom".

Professor Ziman earlier this year had received, in conjunction with Dr John Humphrey (until recently deputy director of the National Institute of Medical Research) and lawyer Paul Sieghart, the second annual Airey Neave award, which will finance a study of freedom in science. He was therefore an obvious proxy for Dr Brailovskii who, until his arrest last November, had acted as host and organizer of the Sunday seminar for Jewish "refusnik" scientists denied emigration visas but dismissed from their academic posts after applying for them.

Professor Ziman said it would have been more appropriate that Dr Brailovskii's proxy should have been not a private scientist such as himself but the president of the Royal Society in his official capacity. He recalled that Dr Aleksandr Voronel', the founder of the Sunday seminar, said in Britain shortly after being allowed to emigrate in 1974 that "the seminar is the only true representative of free and independent science in the Soviet Union". The Royal Society, whose official aim is "improving human knowledge", should therefore, said Professor Ziman, give the fullest possible support to the seminar - support which, so far, it has been reluctant to afford.

Vera Rich

cultures over 10 litres, be eliminated from the guidelines — went further than Dr Baltimore and Dr Campbell had proposed to RAC. Others, such as the continuation of local biosafety procedures and the recommendation that the guidelines remain mandatory for scientists working with NIH funds, are more conservative.

Any decisions by RAC at its next meeting will be subsequently published in the Federal Register for public comment. After that, the matter will rest with Dr Richard M. Krause, director of the National Institute of Allergy and Infectious Diseases, who was given full responsibility for ensuring compliance with the guidelines by Dr Donald Fredrickson when he resigned as NIH director on 30 June.

As the safety debate is being wound down at NIH, a complementary discussion about the steps necessary to prevent undesirable clinical applications of genetic manipulation techniques has been getting under way with the President's Commission for the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research.

The commission was asked last year to look at the ethical issues raised by genetic engineering by President Carter's science adviser, Dr Frank Press, following a letter to the President from three church groups expressing concern that recent advances in genetic research meant that "those who would play God will be tempted as never before". Since then the churches involved have not demonstrated a particularly close interest, but public concern has been stimulated by various press reports of potential new surgical techniques.

At last week's meeting the members discussed a draft report on the ethical and social aspects of genetic engineering. And although reluctant to raise unnecessary fears, they agreed that the implications were likely to be significant — for example in terms of the potential ability of an individual to alter the genetic characteristics of his or her descendants.

Most commission members agreed that there was a need for a wider public dissemination of information about the potential effects of new clinical techniques. Also that it might be appropriate for some type of advisory body to indicate areas in which caution should be used.

There was less of a consensus on whether it was desirable that such a body should suggest that certain types of experiments—for example the cloning of a human being—should be prohibited. Some, for example, suggested that any attempt at what the draft report described as the "control of evolution" should be proscribed; others pointed out the phrase was so broad as to include many currently-accepted practices, such as the treatment of diabetes with insulin.

The commission also debated whether discussions should take place at an international level. There was general agreement, however, that achieving international consensus on the boundary between acceptable and unacceptable practices would be even more difficult than at a national level.

David Dickson

New substance regulations

Industry complains

The British Chemical Industries Association is protesting vigorously at the draft on the notification of new chemical substances drawn up by the Health and Safety Executive. The association claims that the draft regulations would mean the end of research and development in the British chemical industry.

The draft regulations were published last February, when comments from interested parties were invited by the end of this month. They are an attempt to bring British practice into line with a directive of the European Commission, whose aim is to protect "man and the environment" from the potential hazards of new substances. Although the directive deals chiefly with the protection of the consumer, the Health and Safety Executive is (given its remit) primarily concerned with the protection of workers' health.

Thus the British regulations would require industry to notify not only all new manufactured substances but also all new intermediates in chemical processes. The Chemical Industries Association complains that the extra costs involved will drive research and development away from Britain. The dilemma is, however, real. The Health and Safety Executive says that intermediates must be tested if existing regulations to protect workers from potential hazards are to be put on a more formal basis than required by the Health and Safety at Work Act.

The consultative document is precise about the tests required for new chemicals. Manufacturers would be required to assess the toxicity of substances by LD₅₀ tests, provide data on skin and eye irritability, tests for mutagenicity and possibly carcinogenicity and teratogenicity. They would also have to provide data on biodegradability. The executive estimates that the total cost would be about £45,000 per substance.

The objections of the chemical industry appear to centre more on the range of chemicals covered than the direct cost. As well as chemical intermediates, the draft regulations cover pharmaceuticals, foodstuffs and pesticides, all of which are excluded from the European directive on the grounds that they are covered by other regulations. The Health and Safety Executive's argument is that such assessments relate only to specific uses, and are not necessarily sufficient.

After the July deadline, the chemical industry will also be arguing for a strengthening of the provisions for preserving confidentiality. The association is concerned that valuable data, especially those on intermediates which would provide information on novel process routes, could fall into competitors' hands.

So far, few other bodies have put in comments, but the trade unions and environmentalists will also be having their say. The controversy aroused by the chemical industry's response, however, suggests that further negotiation will be needed before the regulations are in a final form and that the European Commission's 18 September deadline for the implementation of legislation will not now be met.

The European Commission is at the same time going ahead with its plan to compile a catalogue of all chemicals manufactured in Europe. Thereafter, industry will be required to notify the commission of all new chemicals manufactured during the past ten years that are not included, a ruling that will apply even in countries that will not have introduced their own legislation.

Judy Redfearn

UK pharmaceutical industry

Keeping up

"Britain's medicine makers have brought out an 'unfashionable' annual report — it tells a success story." So says the cheery publicity blurb announcing the 1980–81 report of the Association of the British Pharmaceutical Industry (ABPI). The claimed success is an increase in the value of exports of pharmaceuticals to £745.4 million in 1980, 16.7 per cent up on the sales in 1979, and representing a £523 million surplus of exports over imports.

Evidence of success is rare enough in British industry and the bouncy confidence affected by ABPI is likely to please a government eager for good news. And the industry seems to be getting its views across with some aplomb. Already this year the industry has had a victory in the form of new regulations governing the granting of the clinical trial certificates which must be obtained before new drugs can be tested clinically. From March, the certification process requires simpler documentation and data requirements have been reduced.

In another area of concern to ABPI, Mrs Sally Oppenheim, Minister of State for Consumer Affairs, has said that the government will try to include a "state of the art" defence in the EEC directive on product liability. The objective is that manufacturers should not be held liable for injuries to health caused by a product which could not be termed "defective" in the light of scientific knowledge when the drug was put onto the market.

The supposed main benefits to be gained by the simpler clinical certification rules are a reduction in the 10 to 12 years now needed for a new drug to reach the patient (a debatable improvement, especially after Fisons' withdrawal of Proxicromil when it was all but on the market, see *Nature* 12 March, p.81), and a stimulus to encourage development of drugs to treat less common diseases.

However, the most tangible effect of relaxations in control of drugs in clinical trials is likely to be an increase in the numbers of trials conducted in the United Kingdom rather than in other, less restrictive, countries. This is one factor to be considered by multinational companies when deciding whether to invest in Britain or go elsewhere. At present investment in research in the United Kingdom is holding up well, with £16 million to be invested by Merck, Sharp and Dohme in a neurobiology research centre near Harlow, £5 million by Upjohn in expanding facilities at West Crawley, £10 million by the Wellcome Foundation in a chemical research laboratory in Beckenham, and £3.3 million by Roche in improving research facilities at Welwyn Garden City. But competition between the developed countries for the favours of the researchbased companies can only increase.

Charles Wenz

Industry and research

Dupont joins in

Boston

Reflecting the growing eagerness of industry and universities to find ways in which both can profit from advances in biotechnology, the chemical company Dupont has promised \$6 million for genetic engineering research to a group of workers at Massachusetts General Hospital, one of the teaching hospitals associated with Harvard University. This announcement comes just as scientists, politicians and university administrators are completing their examination of a ten-year, \$50 million grant to another group of Harvard geneticists proposed by the German pharmaceutical house Hoechst-Roussel (see Nature 18 June, p. 525).

The Dupont grant will support the new genetics department at the Harvard Medical School under Dr Philip Leder who is moving to Harvard in September from the National Institutes of Health. The conditions of the Dupont deal are similar to the Hoechst arrangement; the grant recipients retain patent rights on discoveries made with corporate funds, but the companies are given exclusive licences to develop any products that result. One difference in the Dupont grant is that the company has not requested training positions for its scientists.

Although most university officials applaud these agreements, in the past month committees in both the Senate and the House of Representatives, officials of the National Institutes of Health and high ranking university officials from the United States and Canada have met independently to review Harvard's new affiliations with industry and to question whether the quality and independence of research will be compromised by corporate support.

These hearings have attracted wide attention since Senator William Hatch complained that the Harvard-Hoechst grant fostered a "technology leak" by giving a German company first crack at exploiting discoveries at institutions supported by public funds. The victims of such a situation, he suggested, would be the US taxpayers who have indirectly supported basic research that will benefit foreign investors.

This concern will not be a problem with the Dupont grant, because the money will be coming from a US chemical and drug conglomerate. Dupont plans to give Harvard the \$6 million in annual instalments, with \$2 million immediately and \$1 million over each of the next four years.

University officials say that they will examine all patentable discoveries very carefully to determine whether they were made with federal funds or portions of the Dupont grant. Only the latter will bring Dupont exclusive licensing rights to

university-owned patents.

The toughest scrutiny, however, may come from the local city councils. The Cambridge City Council has officially ordered an investigation of Harvard genesplicing experiments in tax-exempt laboratories. Council members intend to rescind tax exemptions where private corporations will reap financial benefits.

Harvard officials do not anticipate an investigation of the Dupont grant similar to the House investigation of the Massachusetts General Hospital-Hoechst agreement.

Michael D. Stein

Chinese Academy of Sciences

Scientist takes over

China's Academy of Sciences once more has a scientist at its head. A few weeks ago the academy's Scientific Council met for the first time for 21 years and elected as its president Dr Lu Jiaxi, a physicist, who at one time worked at University College London under Professor S. Sugden and at the California Institute of Technology under Linus Pauling.

Dr Lu takes over the presidency from Fang Yi, the minister responsible for the State Commission for Science and Technology. On resigning, Minister Fang stressed that the presidency should be an elected post (he had been a government appointee) and should go to a scientist.

At the same meeting, the Scientific Council accepted a draft constitution which states that the supreme decision-making power for the academy will be vested in the 400-strong council, which from now on should meet every two years. Between council meetings, the academy will be administered by a presidium of 30 members, of whom 20 will be members of the council and 10 from the Communist party and government departments.

These changes reflect an overall policy of increasing the professionalism and prestige of Chinese science, which suffered considerably during the Cultural Revolution of 1966-1976. As well as revitalizing the Academy of Sciences, recent developments include the conversion of a teacher's training college in Hainan into a university, which will commence undergraduate enrolment in autumn 1983 and major discussions on how to develop vocational and technical secondary education. This latter need is so pressing that one government spokesman suggested that in addition to the state system, private projects for training technical workers should be encouraged. And to help young people develop their interest in science, a new "National Association of Science Coaches for Juveniles" was established in Peking, with Jiang Nanxiang, the Minister of Education as Honorary Chairman, and Wu Zhonghua, executive chairman of the Presidium of the Academy of Sciences as chairman of the Board of Directors.

Spanish research

Painful reform

Barcelona

The Spanish Higher Research Council (Consejo Superior de Investigaciones Científicas (CSIC) is nearing the end of a process aimed at giving it a fresh start. The reformers, the present directorate of CSIC, intend to demonstrate to public opinion and to the government that CSIC can renew itself and become an efficient instrument in the economic and cultural development of Spain.

CSIC is the main public body devoted to research in Spain. It has a permanent staff of 5,000 (1,500 of them scientists) in about a hundred institutes. Since its foundation and haphazard development during the government of General Franco, CSIC has maintained an enormous diversity of research interests of variable quality. There are groups devoted to local studies and to theology, to textile technology and fisheries and also to history, biology and physics. Only a few of these institutes can be compared with advanced European or American laboratories, and most of them suffer from limited and ageing staff and poor funding. This has provoked criticism from both inside and outside CSIC. directed chiefly at the low scientific level of many institutes and their lack of relevance to the general needs of the country. During the past five years of democratic government, even the aboltion of CSIC has been openly discussed.

A move to reverse this trend from inside CSIC began after the appointment of a new directorate last year. CSIC's Scientific Commission, consisting of scientists from different areas of research, was asked to suggest important areas of research and to advise laboratories how they might best pursue them. A number of commissions are now working on detailed programmes based on these suggestions. As CSIC's budget cannot finance all the programmes chosen, it is hoped that outside agencies will be able to provide additional funds. It is hoped that groups will join forces to produce plans that are likely to be financed.

CSIC scientists are anxious to give the proposed changes a chance of success, but there is some doubt about the speed at which the scheme is being carried out, particularly in the absence of any long-term decision at government level.

Increases of staff are unlikely because of cuts in public expenditure and there is doubt as to whether the proposed Law of University, including to provide guidelines for recruiting teaching and research staff, will be passed before the next elections in 1983. In the meantime, the need of people and the low level of salaries are increasing tension inside CSIC and could lead to the resignation of the present directorate. A welcome reform lies on a knife-edge.

Unfair on DeVita

Sig — The recent US Senate hearings in which Dr Vincent DeVita was scourged for the failure of the NIH-NCI bureaucracy to vitiate promptly an accused laboratory cheat leaves one appalled and apprehensive. Dr DeVita is the first NCI director who is a clinical oncologist, an occupation faced with the unenviable repetitive experience of patients who become progressively worse, mortify and die. In no small part due to the efforts of Dr DeVita and the organization he has assembled, this nó longer takes the invariable course it once did and the concept of a cure has become realistic for many cancer patients. He has tried to redirect the cancer research industry back to the human cancer patient and away from highvisibility science for science's sake, while still juggling the all important basic research that must be done as well. To hear of his being chastized in such a silly way can be best compared to rejecting Socratic reasoning because Socrates may have been bald.

Serbian exchange

Sir - We would like to report on the great value of a recent exchange visit between British and Yugoslav geologists. In May we took part in a ten-day field trip to Yugoslavia, organized jointly as part of an agreement between the Royal Society of London and the Council of Academies of Science and Arts of the Federative Socialist Republic of Yugoslavia. It followed a visit in autumn 1980 when Yugoslav geologists Professor V. Majer and S. Karamata came to the UK, the first time that such an exchange had occurred between geologists of these countries.

Our time was spent in Yugoslavia mostly on a geological excursion through Serbia by minibus organized by Professor S. Karamata of the Faculty of Mining and Geology at Belgrade University. A round trip of over 2,100 km was made, starting from Belgrade and passing through the Carpatho-Balkan chain, the Serbo-Macedonian massif and the Inner and eastern Outer Dinarides. Stops were made at selected localities of interest enabling the international team of British, French, Hungarian and Yugoslav geologists to exchange ideas and collect rock samples. The lithology observed ranged from Palaeozoic basement, Mesozoic lavas and sediments and Cenozoic calc-alkaline flows to ultramafic, mafic and metamorphic components of ophiolites and related olistostromes.

This traverse enabled us to obtain an excellent introduction to the geology of Yugoslavia — an essential part of studies in the Earth sciences where it is necessary to observe at first hand natural phenomena in the field. We hope this initial exchange will lead to further visits and joint research in the near future.

Human protection

Sir — An imprecise reference in a recent article, "NIH censure for Dr Martin Cline," (Nature 4 June, p.269) prompts us to delineate the distinction between the UCLA School of Medicine Human Subject Protection Committee which reviews research protocols involving human subjects for risk-benefit ratio and the UCLA Human Subject Policy Committee which, based on federal regulations, develops university policy governing research involving human subjects.

ESTHER F. HAYS

Human Subject Protection Committee, School of Medicine. University of California, Los Angeles, USA

Fight the obscure

Sir - Recognizing the present popularity of various forms of anti-scientific obscurantism, both here and still more in his own country, Dr Ralph Lewis was dead right to conclude his letter (Nature 11 June, p.448): "We must find and state clearly our fundamental agreements, so that our differences in presentation cannot be misconstrued and distorted".

I suggest that one first necessary step is to insist always that the contrary of any evolutionary account of the origin of species is a doctrine of special creation. Evolution in this understanding would be decisively refuted were palaeontologists to discover fossil remains of creatures morphologically indistinguishable from the higher mammals in rocks which are much too old - J.B.S. Haldane used to specify human remains in a coal seam. Darwinian and any alternative accounts of the mechanism of such evolution, or of its mechanisms - the Lamarckian inheritance of acquired characteristics, for instance - must all be equally inconsistent with any doctrine of special creation. And, although I will not myself pretend to understand cladistics, we can be sure that its Marxist adherents are not rooting for special creation as opposed to evolution. Their point against Darwin is, surely, that while he defended "that old canon in natural history, Natura non facit saltum", they themselves are committed to the opposite contention, that both Nature and humanity sometimes take 'A great leap forward''

A second step is to dispose of certain philosophical muddles and misconceptions such as those propagated by the British Museum (Natural History). Barry Cox quoted several in his report (Nature 4 June, p.373). One is that the assertion of the survival of the fittest is vacuously tautological: "The Survival of the Fittest is an empty phrase, it is a play upon words". Certainly, since the criterion of fitness to survive is here actual survival, this assertion is not to be construed as an assurance that all is for the best. It is, nevertheless, not a tautology. For clearly it denies that the survivors survive at random, while asserting that they have some sort of competitive edge over the non-survivors.

Again, Cox quotes the statement: "The idea of evolution by natural selection is a matter of logic, not science, and it follows that the concept of evolution by natural selection is not, strictly speaking, scientific". Certainly it is possible formally to deduce the conclusion

that some natural selection must occur from two or three general propositions about multiplicative reproduction, variation, and the finitude of resources. But this neither disqualifies that conclusion as science nor turns it into an empty truth of logic Substantial truths can be and are deduced with perfect formal validity from premises stating other similarly substantial truths.

Defining a lectin

Sir - The Nomenclature Committee of the International Union of Biochemistry has discussed the objections raised by Kocourek and Hořejší to the definition of lectins proposed by Goldstein et al. 2 which was also published by the Nomenclature Committee in its 1981 Newsletter3.

According to both definitions, "a lectin is a sugar-binding protein of non-immune origin' (glycoproteins are a class of proteins and there is no need to specify them in the definition). The emphasis in the definition of Goldstein et al. is an operational one, so the definition is easy to apply experimentally by the criteria of agglutination of cells (not necessarily of erythrocytes, which carry a limited variety of sugars on their surface) or precipitation of glycoconjugates. By contrast, the criterion of Kocourek and Hořejší of lack of enzymatic activity is difficult to apply; for example, glycosyltransferase activity might be present with an acceptor different from those tested. Moreover, there is now evidence that certain proteins hitherto known as lectins possess glycosidase activity4

The definition of Goldstein et al. implies the presence of more than one carbohydratebinding site. Strictly speaking, it excludes proteins such as ricin that are closely related to lectins in certain properties (for example, acid composition and possibly primary structure) and derived from the same plants, and this may be a disadvantage. Nevertheless the definition of Kocourek and Hořejší is so close to meaning "carbohydrate-binding protein" that a special name seems unnecessary, and the definition is too broad to be useful, since it includes substances such as sugar-transport proteins, chemotaxis receptors, certain bacterial toxins, hormones and interferons.

As long as we do not know with certainty the role of lectins, whether in plants, animals or microorganisms, it seems preferable to focus the definition of these substances on positive and easily testable properties. We therefore plan to continue to use the word as proposed by Goldstein et al.

NEWS AND VIEWS

Hydrothermal processes on ridge flanks: the *Challenger*'s return to the Costa Rica rift

from Roger N. Anderson

This coming November the drilling vessel Glomar Challenger will reoccupy a site which has already produced some of the most spectacular scientific discoveries of the highly successful International Phase of Ocean Drilling of the Deep Sea Drilling Project. The drill site, located on the south flank of the Costa Rica Rift in the eastern Equatorial Pacific, is being used to investigate a paradox within plate tectonics.

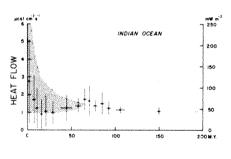

Ten years ago it was discovered that regardless of its location or tectonic setting, the depth of any normal sea floor is only a function of its age^{1,2}. This elevation change is due solely to thermal contraction accompanying cooling as crust spreads from mid-ocean Theoretically, the heat flow measured along the top surface of the lithosphere should decrease exponentially from a maximum at spreading centres to low values in old ocean basins. Instead, as is well illustrated in a compilation prepared by M. Hobart (Lamont-Doherty Geological Observatory), observations (see the figure) show an entirely different form of cooling is taking place. Conductive heat flow is actually lowest near spreading centres, and increases to that predicted by plate tectonics as the lithosphere ages³. The 'missing heat' near midocean ridges is carried away by the hydrothermal convection of seawater through the oceanic crust and sediments4. With ageing, however, each plate somehow becomes sealed from this convective hydrothermal circulation and from then on the measured conductive heat flow matches that predicted by conventional lithospheric plate models.

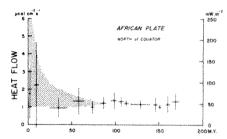

This is no minor event since more than one-third of the entire sea floor of the

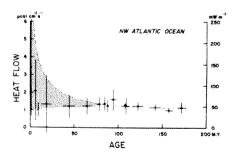

world's oceans contains a currently active convection system⁴. Every drop of the vast volume of ocean water passes through the oceanic crust in a few million years⁵. The crustal basalt consequently buffers the composition of the ocean water and is a more important source of marine chemicals than the input from rivers⁶. In addition, metallogenesis accompanying the discharge of these convective fluids from the crust into the ocean probably forms one of the Earth's major ore generation mechanisms⁷. The ocean water captured chemically within the oceanic

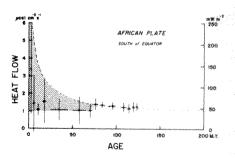

crust even reappears to affect man's day to day life. Volcanicity above lithospheric subduction zones is directly caused by the catalytic effect of seawater released by chemical reactions deep within the mantle⁸. Water vapour accompanying the eruption of Mt St Helens originally circulated through and was caught up in oceanic crust in the Pacific Ocean as part of a ridge flank convection cell before its eventual subduction beneath Washington and Oregon.

In 1979, during drilling legs 68-70, the Glomar Challenger investigated the Costa

Solid dots are regional averages of observed heat flow over the age intervals spanned by the horizontal bars. Vertical bars are ± 1 standard deviation of the data from the mean. Indian Ocean is for all plates in that ocean³. Northwest Atlantic is American Plate only. African Plate north of equator is in the Northeast Atlantic and African Plate South of the equator is in the Southeast Atlantic Ocean. Exponential decay of heaf flow away from midocean ridges (dashed curve) is predicted by theoretical lithospheric plate models^{1,2}. Stipled region is the 'missing convective heat flow' component not measured by current observational techniques which only detect conductive heat transfer. With ageing, this convective hydrothermal circulation becomes sealed and we see a transition from predominantly convective to conductive heat flow. From then on, the observed heat flow matches the predicted values.

Roger N. Anderson is senior research associate at Lamont-Doherty Geological Observatory and adjunct associate professor in the Department of Geological Sciences of Columbia University, New York.

Rica Rift, the youngest known transition zone from convective to conductive sea floor heat flow. Two possible mechanisms could explain the transition - either a thick sedimentary blanket forms a hydraulic lid sealing convection within the oceanic crust and/or the basaltic 'plumbing system' becomes plugged by metamorphic alteration9. Only drilling would allow direct observations to be made.

Papers presented at the American Geophysical Union's spring meeting in Baltimore reported some astonishing discoveries from the integrated set of in situ geophysical and geochemical experiments carried out during these legs. M. Langseth (Lamont-Doherty Geological Observatory) et al. 10 began by presenting temperature logging results which showed that seawater was being naturally drawn down the drillstring into the oceanic crust beneath 300 m of mud and chert at site 504B. The downflow rate of 6 m3 h-1 was unchanged 54 days later when leg 70 reoccupied the site and it is anticipated that it will be continuing when the Challenger returns in November 1981.

Pore pressures 10 bars less than hydrostatic pressure as measured in situ across a hydraulically packed section of the wellbore were responsible for the downflow (M. Zoback, US Geological Survey and R. Anderson, ref. 11). Most of the downflow was disappearing into an acquifer 50 m below the sedimentbasement interface. Direct measurements showed the basalt to be several orders-ofmagnitude more permeable than the overlying sediment and chert layers11. Convection in an oceanic crust with permeability of 2-40 millidarcies (determined by the measurements) can indeed account for the observed underpressures, as shown by D. Gartling (Sandia Labs) from Finite Element Convection Modelling. It thus appears that the Challenger penetrated through a hydraulic lid into an active convection system. Interestingly, most of the real extent of such a cell is predicted to be underpressured. Thus, many, many Challenger holes drilled previously in the world's oceans may have also penetrated underpressure zones, though few measurements were ever made which might have detected such a phenomenon.

The oceanic crust does show major changes with depth, however, which must affect the form of convection. R. Von Herzen (Woods Hole Oceanographic Institution) et al. 12 measured a steady porosity decrease with depth from a long spacing electrical resistivity experiment. Anderson and Zoback¹³, using ultrasonic borehole televiewer imagery for the first time down a Challenger hole, found that a marked increase in seismic velocity downwards in the upper 200 m of the oceanic crust (layer 2A) was caused by replacement of seawater with clay and alteration products in fractures and voids at site 504B. R. Stephen (Woods Hole and see ref. 14) conducted an 'oblique' seismic experiment, shooting explosives from a surface ship to receivers latched into the wellbore. His results showed unusually high seismic velocities 1-2 km into the oceanic crust at this site. These may result from metamorphic alteration of the oceanic crust accompanying cellular convection.

J. Honnorez (University of Miami and see ref. 15) and M. Mottl (Woods Hole and see ref. 16) presented geochemical evidence for major chemical and alteration gradients both downhole and between four holes within one kilometre of each other at site 504B. These horizontal gradients probably result from heterogeneity caused by active hydrothermal convection. For example, Mottl predicts a major source of Ca-rich pore fluids somewhere just to the west of the drill sites. That source is probably the upwelling limb of a convection cell, the waters of which have travelled deep into the oceanic crust, reacted with basalt and then returned towards the surface of the basalt. Similarly, Honnorez reported marked increases in the 'grade' of alteration downhole with some of the 'hottest' metamorphic grades ever found in the drilling project (+ alc) encountered at the bottom of 504B.

It is unfortunate that 500 holes were drilled in the oceans before downhole experiments such as those using packers, televiewers, borehole seismometers and long period resistivity logs were attempted, but the spectacular success of such in situ observations, coupled with the powerful geochemical sampling and analysis techniques now available, promise to add a truly new dimension to deep-sea drilling as a scientific tool. The return to Costa Rica will very probably produce two kilometre penetration into the oceanic crust, with a full set of in situ experiments.

By then, more than 105 m3 of seawater will have been drawn into the oceanic basalt below the sea floor, never again to reappear in the ocean as long as the chert and sedimentary lid remain intact.

Such huge natural reservoirs have great potential as sites for the disposal of toxic wastes and offer several advantages over present proposals for land-based sites. The natural underpressures will draw seawater or wastes into the oceanic crust and if the seal is broken accidentally (by an unexpected earthquake, for example) oceanic bottom water will flow downwards into the crust rather than allowing toxic waste to escape into the ocean. Any natural heating which might accompany toxic waste burial should enhance the seal since it would convert more and more sediment into chert above the disposal cell and increase the seal's thickness. Once toxic waste was drawn into the immense oceanic crustal convection cell, its residence time would be far longer than the time for which it might endanger the environment.

Verification of these advantages is still awaited, of course, but the return of the Challenger to the Costa Rica Rift site should greatly help our evaluation of such deep-sea disposal sites.

Solar physics at Oxford

from I.W. Roxburgh and C. Jordan

THE growing importance of solar physics within astronomy was illustrated by a recent meeting* at Oxford which took as its theme 'Solar Activity'. Topics ranged from the underlying causes of solar activity in the interaction between the sub-photospheric convection zone and magnetic fields to the solar flares, the highest energy manifestation of the active Sun.

Weiss (University of Cambridge) described recent theoretical work on turbulent magneto-convection. Attention is now turning from the systematic largescale fields, rooted deep in the convective zone, to the small-scale feature such as ephemeral active regions. Recent results suggest that these small flux loops are examples of the intermittent turbulent magnetic fields in the upper part of the convective zone, where magnetic flux has been confined to isolated ropes winding between convective eddies.

Bruzek and Schröter (Kippenheur Institut, Freiburg) stressed the current view of solar active regions developing through the emergence and expansion of new magnetic flux. In the higher layers of the transition region and corona active region

fields show as distinct loop structures. Substantial progress has been made in determining the temperature and density structure of these loops, and in understanding their stability(Monsignori-Fossi, Arcetri Observatory). Controversy remains concerning how much information on the heafing processes can be obtained from analyses of emission line fluxes. This is an area where further highresolution observations are required, particularly time-dependent measurements of line profiles. Maltby (University of Oslo) stressed the same point with respect to the energy balance in sunspots. Gurman (Goddard Space Flight Center) reported observing, with the UVSP instrument on the Solar Maximum Mission satellite, oscillations with periods of 120 to 180 seconds in fluxes and velocities measured in the chromosphere-corona transition region over a sunspot. It has proved difficult to detect oscillations in the quiet sun with previous satellites. Thomas and Scheuer (University of Rochester) presented results of calculations which show that oscillations could be caused by resonant behaviour due to the strong vertical trapping of wave energy. Both Maltby and Stenflo (University of Zurich) drew attention to the importance of current and future measurements of the solar irradiance from spacecraft in understanding the sunspot flux deficit.

Solar flares represent the most extreme form of activity and several reviews were given of recent results from the Solar Maximum Mission satellite. This satellite has for the first time allowed the simultaneous study of active regions and flares over a broad spectral range and thus over a range of heights and temperatures in the atmosphere. Whilst spectroscopic methods are revealing the temperature and density conditions during flares, the imaging instruments are being used to show where and when flares occur in relation to the longer-term development of particular active regions. In particular, the identification by the hard X-ray imaging spectrometer team of the source of hard X rays with the foot-points of loops, rather than with the region producing softer X-ray emission, will limit the choice of suitable models for the hard X-ray emission. Measurements of Fe Ka emission caused by fluorescence and the first resolved spectra of the Fe xxvi resonance plus di-electronic satellite lines were also reported by the X-ray polychrometer team.

Before the meeting, delegates from all parts of Europe discussed their plans for the rest of the 1980s. A remarkable consensus emerged concerning important priorities including, for example, measurements of velocity fields and magnetic fields related to the development of emerging

I.W. Roxburgh is Head of the Department of Applied Mathematics at Queen Mary College, London and C. Jordan is lecturer in the Department of Theoretical Physics, University of Oxford. magnetic flux; and studies of small magnetic elements in the convective super-granulation structure.

Of the ground-based programmes the most ambitious concerns the development of a large European Solar Telescope which would offer European solar physicists a high-resolution telescope situated in the Canary Islands. This project can be seen as a logical extension of the previous sitetesting activities of the Joint Organization for a Solar Observatory.

Several countries will continue to participate in the USSR's Interkosmos and Prognoz series of rockets and satellites, with particular interest in X-ray imaging and spectroscopy. The community within the European Space Agency is awaiting the outcome of representations to NASA concerning the US part of the two-spacecraft International Solar Polar Mission. The US spacecraft, which is due to carry out experiments to study the corona near the Sun, is

threatened by recent budget cuts.

The strength of theoretical solar physics in Europe and its close involvement in analysis of new data are particularly encouraging since they should allow a good return from participation in a variety of guest investigator programmes as opportunities arise.

There is keen European interest in two potential solar payloads for the Shuttle Spacelab: in the Solar Optical Telescope, at present under study within NASA, and in the complementary Grazing Incidence Solar Telescope, currently a potential ESA project. The future of these missions depends on the success of the Shuttle; the participants abandoned the dining hall at 7.10 on Tuesday, 14th April, to crowd round the television set and witness the safe return of the first Shuttle flight. With some relief the participants returned to continue their dinner and polish up their proposals for future experiments.

Glueballs, anyone?

from T.F. Walsh

THE QUARK MODEL, invented in 1963 by George Zweig and Murray Gell-Mann, has gradually grown into a theory of elementary particles. It is now called quantum chromodynamics. An essential element of the theory was provided by Yoichiro Nambu in 1966. He suggested that the quarks are bound together in particles by the exchange of spin one vector particles, which have a new quantum number unlike the conventional isotopic spin, strangeness and so forth typical of the quarks. Nambu's exact model has been discarded by most physicists, but the idea remains.

The vector particles which bind quarks are now called gluons and their quantum number is called colour. Gluons interact strongly with quarks over distances of 10-13 cm, binding them into particles. Quarks and gluons are thought not to exist as free particles, but only inside the known 'colourless' particles, although this has yet to be proved. As well as their interaction with quarks, gluons interact strongly with each other. They should therefore bind into particles even without quarks. These particles, made entirely of gluons, have not yet been seen, but there is a strong conviction among particle physicists that they do exist. They are called bound glue states, gluonia or glueballs. They are a new type of elementary particle and it is very important to look for them.

A recent issue of *Physical Review Letters* contained two papers on glueballs, by K.

T. F. Walsh is a visiting scientist at CERN, Geneva.

Ishikawa at DESY in Hamburg and by M. Chanowitz at the Lawrence Laboratory in Berkeley^{1,2}. Chanowitz' paper is entitled "Have We Seen Our First Glueball?" Indeed, have we? And why should the first one be seen now, after hundreds of quark states have been tabulated in the celebrated Particle Data Group tables?

If glueballs do exist, it is important to know where to look for them. According to quantum chromodynamics, heavy particles like the J/Ψ and the Υ mesons can only decay first to gluons, or a photon and gluons, which then materialize into conventional mesons. The decay of the J/Ψ meson into a photon and two gluons ought to be a good place to look for glueballs. If the two gluons materialize into ordinary mesons through the intermediary of a glueball, experimenters ought to see a nearly monoenergetic photon recoiling against a resonance which decays to mesons. The chain would look like this:

It has even been suggested that the two gluons should in some way maximally generate glueballs in this chain and that the production of mesons made of quarks should be much smaller than the glueball production. According to this view, one per cent of J/Ψ decays would contain a glueball (there might, of course, be several glueballs visible at different masses)³⁻⁵. If only gluons

maximally generate glueballs, that would explain why they have not been seen until now; J/Ψ and the Υ , themselves only recently discovered, would be the first good sources of glueballs. It has also been pointed out that the glueballs produced in this reaction would mostly have spin two, with the production of spinless glueballs slightly suppressed⁶.

Experimenters have studied J/ Ψ decays since 1974, and decays to a photon and the eta, the eta prime and the f(1250) meson (the 1250 stands for the mass in MeV) have been seen. They are produced at a rather low rate and are all well known quark states (although there is a bit of doubt about the eta prime). Recently, groups working at the SPEAR e⁺e⁻ storage ring in Stanford, California found the decays

J/ Ψ→KKπ J/ Ψ→ηππ

where the $K\bar{K}\pi$ (and, less clearly, $\eta\pi\pi$) form a narrow resonance of mass 1,440± 15 MeV and width $50\pm\frac{30}{20}$ MeV. This was a great surprise, because there is a very obscure state called the E(1420) in the particle tables, and it has roughly these parameters, although there is no convincing evidence that it decays to $\eta \pi \pi$. Why should this obscure state appear together with the well known eta, eta prime and f(1250)?

One might guess that the new state seen in J/Ψ decay is the same as the known E(1420), and that this particle is one of the long sought glueballs. However, careful examination of the experimental data shows that this interpretation cannot be correct if one does not want to upset well established ideas about the production of mesons in, for example, πp collisions. Chanowitz and Ishikawa suggest that there are two mesons of mass around 1,420 MeV. One of them is listed in the data tables, and it has spin one and even parity. It decays to $KK\pi$ but not (or seldom) to $\eta\pi\pi$. The other meson is new, seen only in J/Ψ decay (and maybe in old pp annihilation experiments at low energy). Chanowitz calls this new particle G(1440), and both authors claim that it is a spin-zero glueball of negative parity. It decays to $K\bar{K}\pi$ and also to $\eta\pi\pi$. Neither author claims to prove that there are two different mesons here - what they do is to try to square the unexpected appearance of the state in J/Ψ decay with prevalent theoretical ideas.

What next? The authors suggest several steps. First, the spin and parity of the resonance seen in J/Ψdecay should be checked. If it is 0- and the spin parity assignment of the E(1420) is really 1 $^+$, then the one seen in J/\Pdecay is definitely a new particle. Evidence that the old E(1420) and the new state decay with different rates to

ηππ would supprt this. Also, if the state seen in J/Ψ decay is 0-, it will be seen in the photon-photon process

e+e- → e+e- + "G(1440)"

in the channels $KK\pi$ and $n\pi\pi$. In this process, the colliding electron and positron act as sources of photons, which then create particles. That is why the electron and positron come out of the reaction, only slightly reduced in energy having each given up a photon to make the particle. This reaction is useful because the spin-one E(1420) is forbidden to appear by a theorem of C.N. Yang which says that a vector particle cannot couple to the two photons in this reaction. According to theoretical ideas, a glueball will not appear at a large rate in this reaction, but the

estimate of Ishikawa indicates that it can be seen. Finally, Chanowitz emphasizes that one should look for the proposed new G(1440) in gluon jets, available in the threeiet events seen at the electron-positron storage ring PETRA in Hamburg, and in decays of the \(\gamma \) meson. Again, gluons should be a good source of glueballs.

If all these experimental proposals work out and there is a new particle, G(1440), made as a glueball should be, then we will indeed have seen our first glueball. And more will follow — at the very least a spin-two glueball which is expected to be produced with a significant rate in J/Ψ decay. This would provide a welcome confirmation of the ideas of quantum chromodynamics and new impulses for its further development.

New morphological transition at the Curie temperature

from Mildred S. Dresselhaus

THE increasing sophistication of the techniques of surface science now allow the quantitative study of some long-standing problems. In a recent letter, Hamilton and Jach¹ describe a new kind of structural phase transition on low-angle nickel surfaces at the Curie temperature which gives insight into an effect discovered nearly fifty years ago2. The Hedvall effect is characterized by a discontinuous change in the temperature dependence of the chemical reaction rate (Hedvall Effect I) or as a discontinuous change in activation energy (Hedvall Effect II) at the Curie temperature (T_c) , the temperature of the ferromagneticparamagnetic phase transition. The Hedvall effects are of both theoretical and practical interest as a means to vary or control chemical reactions by external means.

The work of Hamilton and Jach1 is an extension of previous studies by Thapliyal and Blakely3 who showed a reversible morphological transition on a stepped nickel surface using LEED (low energy electron diffraction) as a structural probe and AES (Auger electron spectroscopy) as a surface compositional probe. Hamilton and Jach demonstrated by permeability measurements that this morphological transition occurred at the Curie temperature of nickel. Both studies1,3 focused on vicinal surfaces, defined as single crystal surfaces in the vicinity of lowindex planes. Vicinal surfaces are composed of terraces of low Miller index planes, joined by ledges a few atoms in height. Direct information on terrace widths and step heights is obtained from structure in the LEED patterns, using a kinematic theory of electron scattering from stepped surfaces4.

Mildred S. Dresselhaus is Professor of Electrical Engineering and Director of the Center for Materials Science and Engineering at the Massachusetts Institute of Technology.

The particular vicinal surfaces that were investigated were the Ni(111)5°[110] and Ni(111)10°[110] surfaces, denoting surfaces at 5° and 10° from the (111) plane in the [110] zone, so that the resulting stepped surfaces have (111) terraces and (110) steps. For both of these stepped surfaces, a reversible structural phase transition was observed at the magnetic ordering temperature T_c of the nickel. In the paramagnetic phase, each of the samples exhibited single-atom step heights and narrow terraces, while in the ferromagnetic phase, the Ni(111)10°[110] sample showed a two-atom step height, and the Ni(111)5°[110] sample a four to five-atom average step height and wider terraces.

In addition to this reversible structural transformation, an associated chemical transformation was also reported at $T_c^{1,3}$. To study this transformation, clean nickel surfaces were prepared by argon-ion bombardment, heat treatment and annealing, to yield a surface exhibiting less than 1/20 of a monolayer impurity, as monitored by AES. With the nickel samples in the paramagnetic state, carbon, a dominant impurity in nickel, was found to be dispersed in the bulk of the nickel samples. In contrast, with the nickel in the ferromagnetic phase, carbon from the bulk segregated to the surface, forming a carbon coverage of ~ 0.2 monolayers just below T_{c} but less than 0.003 monolayers of carbon just above T_c . Assuming no entropy change at T due to carbon segregation at the surface, the measured carbon coverage implies a change of greater than 0.2 eV per carbon atom in the heat of segregation at the Curie point.

This change in binding of a surface atom at the magnetic phase transition is also observed in various manifestations of the Hedvall effect, such as studies of the rate of Co sublimation by Sales et al.5, the rate of carbony-

lation of Ni by Mehta et al.6 and the rate of Ni oxidation by Sales et al.7. In all these studies it was found that more energy must be expended to remove a surface atom from a ferromagnetic substrate than from a paramagnetic one. The observations are explained by a lowering of the internal energy of the system as magnetic order is established at the onset of the ferromagnetic state. To overcome this additional binding, more energy must be supplied to remove a surface magnetic atom from a ferromagnetic substrate.

The sublimination of a magnetic species such as cobalt represents an especially attractive process for the study of the magneto-chemical Hedvall effect because of the simplicity of the reaction and because of the removal of the reaction product once the reaction is completed. On the other hand, technical difficulties associated with the high temperature experiment $(T_{c} \sim 1,400 \text{ K for Co})$ had to be overcome to make quantitative measurements. The change in the apparent activation barrier for sublimation on passing through the Curie temperature for Co is 18 kcal per mole or about 0.8 eV per atom. By analysing the temperature dependence of the sublimation rate below and above T_s , Sales et al.5 were able to show that an additional binding energy, $E_m(T)$, was introduced in the ferromagnetic state and associated with the spontaneous ordering of the magnetic moments, $E_m(T)$ $\sim [M(T)/M(0)]^2$, where M(T) is the spontaneous magnetization at temperature T. Because of the rapid change in M(T) near T_c , a large apparent change in activation energies is found near T_c for physically reasonable values of $E_m(0)$, such as 0.2 eV per atom for Co. The magneto-chemical effects associated with this sublimation process have been qualitatively explained in theoretical models by Suhl⁸ and by D'Agliano and Huberman9.

Another chemical reaction for which the reaction product leaves the surface on completion of the reaction is the nickel carbonylation reaction, whereby nickel reacts with CO gas to form gaseous nickel carbonyl. This reaction has the further attractive features of a convenient temperature range (300< T < 440 K) and a Curie temperature controllable by dilution of the nickel with copper (which does not react with CO in this temperature range).

Just as for the sublimation reaction, the nickel carbonylation reaction also shows a change in the apparent activation barrier at the Curie temperature, which in this case is about 0.4 eV per atom. This experiment provides further evidence that an additional activation barrier $E_{\rm m}$ is associated with the ferromagnetic state, insofar as E_m decreases with increasing Cu concentration such that $E_m \rightarrow 0$ for the Cu concentration where $T_c \rightarrow 0$.

Extensive studies of the Hedvall effect have also been carried out on the oxidation of nickel⁷ and of iron¹⁰, yielding general agreement with the basic conclusions of the above magneto-chemical experiments. These oxidation experiments have, however, been more difficult to interpret

quantitatively because of the accumulation of the reaction product at the free oxide surface and the concomitant presence of the additional magnetic barrier at the internal metal-oxide interface.

The identification of a morphological surface transformation at the Curie temperature T_c suggests new insights into the magneto-chemical Hedvall effect because of the enhanced chemical activity at surface steps and kinks. At this point one can only speculate that the discontinuity in the reaction rate at T_c (Hedvall Effect I) might be associated with a morphological change in step size, while a discontinuity in the activation energy or in the derivative of the reaction rate (Hedvall Effect II) corresponds to no morphological change.

Sir Isaac Newton and his madness of 1692 and 1693

from Milo Keynes

By NO MEANS had Sir Isaac Newton a perfect character. William Whiston who succeeded him in his Lucasian professorship at Cambridge said of him that "he was of the most fearful, cautious and suspicious temper"; John Flamsteed, the first Astronomer Royal, declared he was "insidious, ambitious, and excessively covetous of praise, and impatient of contradiction". Even his firm friend, John Locke, wrote that "He is a nice" (that is, difficult and over-precise) "man to deal with, and a little too apt to raise in himself suspicions where there is no ground". There are, however, many instances of his kindness and generosity to others.

Newton had an abnormal dread of controversy, and he wrote to the experimental scientist, Robert Hooke, that "There is nothing I desire to avoid in matters of philosophy more than contention, nor any kind of contention more than one in print". Newton was neurotic, and as John Maynard Keynes wrote1: "His deepest instincts were occult, esoteric, semantic with profound shrinking from the world, a paralysing fear of exposing his thoughts, his beliefs, his discoveries in all nakedness to the inspection and criticism of the world. He parted with and published nothing except under the extreme pressure of friends. Until the second phase of his life (as Master of the Mint in London, and President of the Royal Society), he was a wrapt, consecrated solitary, pursuing his studies by intense introspection with a mental endurance never equalled" Besides all this, he underwent a period of severe emotional and mental disturbance

with sleeplessness and loss of appetite during 1692 and 1693.

In 1693, Newton wrote to Samuel Pepys: "I am extremely troubled at an embroilment I am in, and have neither ate nor slept well this twelve month, nor have I my former consistency of mind, but am now sensible that I must withdraw from your acquaintance, and neither see you nor the rest of my friends any more, if I may but leave them quietly". The same year he wrote to Locke: "Being of the opinion that you endeavoured to embroil me with women and by other means I was so much affected with it as that when one told me that you were sickly and would not live I answered twere better you were dead. I desire you to forgive this incharitableness" Both Pepys and Locke appear to have recognised that Newton's mind was deranged and maintained their friendship for him, and in other letters it is clear his memory was impaired.

It was with the publication of The Correspondence of Sir Isaac Newton2 in 1961 that the period of irrationality could be more fully recognised. Newton was born in 1642 and died in London in 1727. He matriculated at Trinity College. Cambridge in 1661, became Lucasian Professor in 1669, and Fellow of the Royal Society in 1672. He left Cambridge in 1696 to become Master of the Mint in London where "with Pepys and William Lowndes (Secretary to the Treasury) he became one of the greatest and most efficient of our civil servants. He was a very successful investor of funds, surmounting the crisis of the South Sea Bubble, and died a rich man" (Keynes1). He was elected President of the Royal Society in 1703, being annually re-elected for the next 24 years, and in 1705 he was knighted by Queen

Anne — although for political, rather than scientific reasons.

In London, "he reigned as the most famous man of his age, of Europe, and as his powers gradually waned and his affability increased — perhaps of all time, so it seemed to his contemporaries' (Keynes¹), but in the more than 30 years he lived there after leaving Cambridge, his illness of 1692 and 1693, which consisted of insomnia, loss of appetite, loss of memory, melancholia (depression), delusions of persecution, and possibly a trembling in his writing, appears to have been forgotten. After 1693, he still produced copious writings on his mathematical work, on lunar motion, atmospheric refraction and on resisted projectile motion3. He made the corrected Proposition X of the second book of Principia Mathematica in his seventieth year, and recast his theory of the propagation of light between 1705 and 1715. Besides the comment that he spoke very little in company after 1693, there was something rather languid in his look and manner in those years, as shown in a portrait, circa 1689, by Sir Godfrey Kneller in the possession of the Earl of Portsmouth.

Various explanations have been suggested for his illness, predominantly psychological, such as the shock at the death of his mother in 1679, a fire in which he lost some papers (though this occurred far earlier than 1692), his failure to gain various posts such as the Provostship of King's College, Cambridge (which he did not get for the reason he did not attend Eton College as a boy) or the Mastership of the Charterhouse, or simple exhaustion from writing the Principia which was, however, finished in 1687. Clearly, none of these is at all satisfactory, but recently it has been suggested^{4,5} that Newton's nervous breakdown might be explained by mercury poisoning arising from his experiments in alchemy and in making mirrors. Metallic mercury absorption by inhalation as mercury vapour, or by ingestion, can produce neurological, psychiatric, oral and renal signs, and these are reversible when exposure ceases. Mercury is stored in the brain, kidneys and liver, and over a period of time after the poisoning has stopped will continue to appear in hair and nails.

Newton's interest in alchemy was first shown in 1667 when he purchased the six volumes of Zetzner's *Theatrum Chemicum*, as well as chemicals and apparatus, though the first dated chemical experiment in his notebooks was in 1678, with the last in 1696 before he moved to London. He gave up his experiments for nearly two years from May 1684 till April 1686, the period in which he wrote the greatest part of his Principia, but during 18 years he carried out several hundred chemical experiments, with metals playing a large part. It is not always sure from the note books whether the experiments were actually performed, or were just thought of, and often it is not clear any longer what were the chemicals used. It is, however, well recorded that he would heat metals, or their ores, with salts in open vessels, breathing in the fumes and sometimes tasting the formed products. He used to sleep in his 'laboratory' by the fire, which was kept burning for weeks on end while the experiments were going on, and clearly exposed himself to the dangers of metal poisoning.

Newton's great niece, Catherine Conduit, married John Wallop, first Earl of Portsmouth, and as a result Newton's relics and manuscripts mainly passed to the Portsmouth archives. Spargo and Pounds⁵ obtained some of Newton's hairs from the Earl of Portsmouth as well as from Trinity College, Cambridge, and analysed them for mercury, gold, arsenic, antimony and lead. We do not know when the hairs were collected (though we do know Newton kept his hair short in older age which increase the chance that those analysed derived from a time nearer to the experiments), but

raised levels of the metals were found, especially of mercury and lead, and this would be most unlikely, even allowing for contamination from any vessels in which the hairs were stored, in ordinary hairs. It may be added that although some of Newton's symptoms could be caused by lead poisoning, all could be caused by mercury poisoning. We can presume that Newton showed erethismus mercurialis. that is, a timidity especially in the presenceof strangers, but we do not know for certain whether he showed the tremor of mercury poisoning (Hatters' shakes, a condition found among those using mercury in the felt hat industry and from which Lewis Carroll culled his 'Mad Hatter') as his handwriting did not decisively deteriorate during breakdown.

In his recent lengthy biography, Westfall⁶ suggests that Newton's symptoms were simply due to overwork in finishing the Principia in 1687, five years before their onset. This seems an unlikely explanation in view of the delusions Newton suffered and the raised levels of mercury and lead in his hair. The epitaph remains with Newton, who shortly before he died, said: "I do not know what I may appear to the world; but to myself I seem to have been only like a boy, playing on the seashore, and diverting myself, in now and then finding a smoother pebble or a prettier shell than ordinary, while the great ocean of truth lay all undiscovered before me".

Are transport proteins porous?

from N. Michael Green

In the absence of reliable methods for determining molecular size in the lipid bilayer, the state of aggregation of proteins in membranes has proved difficult to determine. A variety of indirect methods have led to conflicting interpretations. Even when the state of aggregation has been established, further experiments are required to clarify its relation, if any, to the function of the protein and even if the oligomeric structure is proved to be essential, the further interesting question of the inter- or intra-subunit location of a transport channel requires an experimental answer.

The difficulty of evaluating the evidence is emphasized by the somewhat conflicting conclusions of two recent reviews. The more wide-ranging article (Klingenberg Nature 290; 449, 1981) considers thirteen membrane proteins or complexes of proteins for which there is evidence for an

N. Michael Green is in the National Institute for Medical Research, Mill Hill, London. oligomeric structure (these include the ADP/ATP carrier, $(Na^+ + K^+)$ - and Ca^{2+} -ATPases, anion carrier (band III), glucose carrier, porin, bacterial rhodopsin, acetylcholine receptor and various cytochrome complexes). The evidence, derived mainly from sedimentation experiments in non-ionic detergents and from cross-linking experiments in membranes, shows that these proteins are all either dimeric, or trimeric, although when the dust settles around the acetylcholine receptor it is likely that each unit of the dimer will be found to be a pentamer.

Klingenberg emphasises the useful conclusions that can be drawn from consideration of symmetry. The vectorial activities of transport proteins imply the absence of symmetry axes from the plane of the membrane and this eliminates dihedral structures from consideration. The popular tetrameric structure for soluble, globular proteins is therefore unlikely to be found among the proteins of membrane transport which must possess cyclic symmetry and a transmembrane

symmetry axis. Such a structure will be stable in a lipid environment only if the intersubunit links include a strong polar component, the symmetry axis providing a plausible location for a polar channel for translocation of substrates.

The accommodation of ligand binding sites and a gating mechanism in a dimeric channel raises a number of interesting questions and leads to the conclusion that there are likely to be only half as many active sites as subunits. Klingenberg develops this argument around the ADP/ATP exchange protein mitochondria which his laboratory has clearly shown to exhibit such half-of-sites reactivity towards the mutually exclusive inhibitors bongkrekate and carboxyatractyloside. The evidence for other carriers is less clear cut and Klingenberg concludes that while the $(Na^+ + K^+)ATP$ as and the glucose carrier of erythrocytes show halfof-sites reactivity, the anion transport protein, the B-galactoside carrier and bacterial rhodopsin probably have separate channels associated with each

Kyte (see this issue of *Nature*, p.201) directs his attention mainly to the $(Na^+ + K^+)ATP$ ase, though he considers his arguments are likely to apply with equal force to the functionally homologous Ca^{2+} -ATPase and $(H^+ + K^+)$ ATPase. He takes a sceptical attitude to the evidence for dimeric structure, pointing out the problems associated with: (1) the large corrections which have to be made for bound detergent and liquid, (2) the underestimation of the molecular weights of intrinsic membrane proteins by gel electrophoresis, and (3) the interpretation of the results of cross-linking experiments in membranes, where intermolecular distances are often very small. Nevertheless he concludes that on balance the evidence does favour a dimeric $(Na^+ + K^+)$ -

The evidence for half-of-sites reactivity is much less convincing, particularly in the light of two recent papers in which the equivalent weight of the ATPase towards ouabain and towards TNPATP has been critically re-evaluated as $180,000 \pm 20,000$. This figure, consistent with one site per 2β protomer, results mainly from use of a more objective method for determining the protein concentration (amino acid analysis) in place of the uncalibrated Lowry method. He also points out that the anti-cooperative kinetics of all three transport ATPases with respect to ATP does not necessarily imply interaction between the two sites on a dimer; it is equally consistent with a monomer in which the ATP site can exist in interconvertible low- and high-affinity conformations. In view of the elusive behaviour of apparent half-of-sites reactivity of globular proteins under critical examination, stronger evidence is required to substantiate it for the $(Na^+ + K^+)ATPase.$

Doubts also surround the Ca²⁺-ATPase of sarcoplasmic reticulum. Although it possesses one ATP site per peptide chain only half of them appear to be phosphorylated in most membrane preparations. Moreover, recent evidence (Pick and Karlish *Biochim. biophys. Acta* **626**, 255) suggests that one mole of covalently bound fluorescein isothiocyanate can block the activity of two peptide chains. On the other hand, the monomer in non-ionic detergent is a fully active ATPase showing steady-state kinetics which differ little from those

of oligomeric preparations.

Of the well characterised transport proteins showing apparent half-of-sites reactivity, only the ADP/ATP exchange protein survives unchallenged; even here the intersubunit channel is no more than the most plausible hypothesis. There is firm structural evidence for the location of the channel in bacterial rhodopsin which functions as a monomer and contains a plausible intrasubunit channel. For the remainder the definitive experiments have still to be devised.

Acid precipitation — a new study from Norway

from J.N.B. Bell

IN THE 1960s the destruction of freshwater fish stocks and the impairment of forest productivity in Scandinavia were blamed on an increase in the acidity of water and soils. It was believed that the increase resulted from 'acid rain' — precipitation containing sulphuric acid derived from the oxidation of SO₂ emitted by the more industrialized European nations. Subsequently there have been similar claims elsewhere, particularly in the northeastern United States and Canada.

Public concern has nowhere been more evident than in Norway, where in the mountainous regions of the south, an accelerating decline in fish stocks has led to the extinction of fish populations in an area of 13,000 km², with severe problems over another 20,000 km². This stimulated the establishment of a major Norwegian interdisciplinary research programme into the biological effects of acid precipitation, which has recently terminated after eight years. The numerous reports published on the findings this project have now been summarized (Overrein, Seip and Tollan Acid precipitation — effects on forest and fish. Final report of the SNSF project 1972-1980).

It is clear from the final report that the SNSF project has made a major contribution towards the understanding of the relationships between the chemistry of precipitation, soils and aquatic ecosystems. The main problems in determining the ecological significance of acid precipitation lie in extrapolating the results of short investigations to the long-term effects of relatively small changes in soil and water chemistry. It has now been established beyond doubt that the precipitation in southern Scandinavia has become more acidic as a result of long-distance transport of air pollution, with

nitrogen oxides contributing an increasing proportion of the acidity. The inputs of H^+ , SO_4^{2+} and NO_5^- are readily estimated by routine analysis of precipitation samples collected at many sites in Norway. However, some uncertainty remains as to the importance of the dry deposition of gaseous and particulate sulphur and nitrogen compounds directly onto vegetation and soils, which may make a substantial contribution to total deposition in some areas.

The report admits that there are few reliable records of the acidity of lake water before 1950 but the marked shift since then towards more acid conditions in areas subject to acid precipitation is well documented. Only five to ten per cent of precipitation in southern Norway falls directly onto lakes and rivers. Thus a thorough understanding of the chemical changes occurring in water when it comes into contact with solids and vegetation is of prime importance when considering the ultimate effect on aquatic ecosystems. A key component of the SNSF project has been the assessment of annual precipitation input and ground-water output into waterways of major ions in selected catchments. It is now apparent that, as well as increased acidity, the mobilization of aluminium from soils by acid water is a major factor in the destruction of fish stocks. The uptake of salt via the gills, necessary to maintain the osmotic balance of the fish, is impaired by acid conditions and is further aggravated by aluminium stimulating the secretion of mucous.

Particularly severe problems are experienced in southern Norway, because a large proportion of the precipitation falls as snow. Pollutants accumulate within the snow-pack during the winter and are subsequently released very rapidly during the short period of snow-melt in the spring, resulting in a flush of acid water into lakes. Knowledge of the hydrology of snow-melt is limited but the SNSF project has

J.N.B. Bell is at the Centre for Environmental Technology, Imperial College of Science and Technology, London. examined the chemical content of successive fractions of melt-water: up to eighty per cent of the pollutant content of a snow-pack may be released in the first thirty per cent of the melt-water, so increasing the threat to the sensitive larval stages of salmon and trout.

The effect of acid precipitation on terrestrial vegetation is less certain. Despite an intensive research programme, the SNSF project provides little support for earlier predictions of massive losses in timber production through leaching of nutrients from soils and direct effects on trees. Most experiments demonstrating adverse effects on soils and plant growth used artifical rain with unrealistically low pH levels. Indeed, in several cases stimulation of plant growth has been observed. The situation is complicated because acid precipitation can increase the availability of plant nutrients by providing inputs of sulphur and nitrogen from the atmosphere and releasing basic cations by weathering of minerals in the soil. It is rather unfortunate that this generally well balanced report implies that acid precipitation must be assumed to reduce tree growth, in the absence of proof to the contrary.

The causal relationship between acid precipitation and the decline of fish stocks has been questioned by Rosenqvist (Sci. Total Environ, 10, 39; 1978), who drew attention to the impact of changes in catchment land use on the chemistry of aquatic systems. During the last one hundred years, many of the Norwegian upland farms, used for summer grazing, have been abandoned and in some cases replaced by conifer woods, which would be expected to accelerate natural soil acidification processes. The SNSF programme has found no consistent pattern which could explain lake acidification on the basis of land use changes. However, an investigation in central Scotland has shown a clear effect of afforestation in increasing stream acidity (Harrison and Morrison in Ecological Impact of Acid Precipitation, eds Drabl and Tollan, SNSF Project, 312; 1980). The report concedes that afforestation may enhance the acidification caused by precipitation. This remains an area of uncertainty and there is a clear need for a better understanding of the relative importance of different sources of

acidification at sites where fish stocks are under stress.

The eight-year SNSF project has. clarified many aspects of the acid precipitation problem. The claims that reduction of fish stocks has been caused by acid precipitation have generally been substantiated, although questions remain concerning the contribution from changes in land use. In contrast, the long-term effect of acid precipitation on forest productivity is far from understood and intensive studies have failed to reveal any clear trends. The SNSF project has predicted that a reduction of at least seventy per cent in H+ and SO₄2 concentrations in precipitation is necessary to restore all lakes to their previous condition: this would involve international changes in energy policy which would encounter severe political obstacles. So far as action within Scandinavia is concerned, attempts to improve the water quality by the addition of lime, followed by restocking with fish, have achieved only limited success and a profitable course may be an extension of a preliminary SNSF programme for breeding strains of trout and salmon tolerant to acid conditions.

"Anthropology: an Introduction to the Study of Man and Civilisation, by Edward Tylor, D.C.L., F.R.S. With Illustrations. (London: Macmillan and Co., 1881.)

To those readers whose knowledge of ethnology or anthropology has been derived from a perusal of Prichard's "Natural History of Man," or the compilations of Wood, Brown, Peschel, or Brace, the present work will present a surprising amount of freshness and originality. They will in fact find themselves introduced to a new and very captivating science.

Andaman Islanders

The first chapter contains a brief sketch of what we learn from history, archaeology, and geology, as to man's antiquity and early condition; and in the next we are shown man's relation to the lower animals both in bodily structure and mental characteristics. The numerous remains now discovered of prehistoric man, and of his works, dating back to an undoubtedly vast antiquity, show us in no case any important deviation from the existing human type, nor any indication that his mental status was lower than (if so low as) that of many living races. At the same time the increasing rudeness of his implements as we go back, undoubtedly indicates that we have

made some approach towards the period when he first emerged from the purely brute state and became "a tool-using animal."

In the next chapter we have an excellent sketch of the chief races of man copiously illustrated by portraits, mostly from photographs and very characteristic. Among the best are those of the Andaman Islanders and the Dyaks, which we here reproduce.

The four chapters on Language, are exceedingly interesting and instructive, especially the account of the gesture language and the illustrations of how connected stories may be told to the deaf-and-dumb quite independently of any knowledge of alphabetical or even verbal signs. In treating of the origin of language Mr. Tylor doubts the sufficiency of the theory that emotional, imitative, and suggestive sounds were the basis on which all languages were founded, though he gives toleraby full illustrations of how roots thus obtained became modified in an infinite variety of ways to serve the growing needs of mankind in expressing their wants or their feelings. Putting aside all mere representations of animal sounds - as the whinny of the colt, the mew of the cat, or the bleat of the sheep consider how clearly do such words as slide, glide, and wave imply slow and continuous motion, the movement of the lips while pronouncing the latter word being a perfect double undulation. How curiously do the tongue and palate seem to be pulled apart from each other while pronouncing the words glue or sticky. How marked is the contrast between the harsh consonants used to express rough, rugged, and gritty, as compared with the soft flow of sounds in smooth, oily, even, polished. Among the Malay races, for instance, in words for large we find a prevalence of broad sounds involving a wide opening of the mouth, as busar, bake, bagut, lamu, elamo, ilahé, erämei, aiyuk, mäina and for small, words that are pronounced quickly and with slight opening of the lips, as kichil, chili, kidi, köi, roit, kemi, anan, kiiti, fek, didiki, all taken from languages of the Malay Archipelago.

The five following chapters treat of the Arts of Life, a subject which Mr. Tylor has to a great extent made his own, and which he discusses in a very interesting manner. The

doctrine of development in the arts is however somewhat strained when it is implied that the modern gun is an outgrowth of the South American or Indian blow-tube; while the origin of bank notes, and the account of the rise and progress of mathematics are hardly anthropology.

The next two chapters discuss the ideas of savage man as to the spirit-world, and the origin and development of myths; while the final chapter gives an admirable sketch of man as a social being, and of the development of that complex organism, Society. This thoughtful chapter cannot be epitomised, but the reader will find in it much curious information as to the sources of many of the customs, laws, and observances of civilised life, which are shown to be often traceable among the lowest savages.

REVIEW ARTICLE

Molecular considerations relevant to the mechanism of active transport

Jack Kyte

Department of Chemistry, D-006, University of California, San Diego, La Jolla, California 92093, USA

A small group of closely related proteins is responsible for all active transport in animal cells, and inorganic cations are the only substances transported by these enzymes. They share a common kinetic mechanism in which two fundamental conformations participate, each receiving and dispatching substrates from its unique side of the membrane. During transport, the cations must pass through their enzyme to cross the membrane and intense interest is currently focused on the possibility that the path which they follow lies within the interface between two discrete subunits in a dimeric structure. Although 'half-of-sites' behaviour, consistent with this hypothesis, has been reported, it is now known that systematic errors were responsible for this mistaken conclusion. The number of protomers which comprise a functional unit of active transport has not been determined.

THE plasma membrane of an animal cell forms the permeability boundary which separates the cytoplasm from the external environment. A diverse collection of metabolites is transported across the plasma membrane by a group of transport proteins, each of which mediates the flux of a specific substrate or group of substrates. Enzymes responsible for the active transport of sodium and potassium¹, calcium^{2,3}, and protons and potassium⁴ have been purified to homogeneity. The minimum stoichiometries for the chemical equilibria catalysed by these enzymes are, respectively:

$$2K_{0}^{+} + 3Na_{i}^{+} + MgATP_{i} \rightleftharpoons MgADP_{i} + P_{i} + 3Na_{0}^{+} + 2K_{i}^{+}$$

$$2Ca_{i}^{2+} + MgATP_{i} \rightleftharpoons MgADP_{i} + P_{i} + 2Ca_{0}^{2+}$$

$$nK_{0}^{+} + nH_{i}^{+} + MgATP_{i} \rightleftharpoons MgADP_{i} + P_{i} + nH_{0}^{+} + nK_{i}^{+}$$

where i and o indicate the cytoplasm and extracytoplasmic spaces, respectively⁴⁻⁶. In broken membrane fragments or preparations dispersed in detergents, these reactions are expressed as a sodium- and potassium-dependent ATPase ((Na⁺+ K⁺)ATPase), a calcium-dependent ATPase (Ca²⁺-ATPase) and a proton- and potassium-dependent ATPase ((H⁺+ K⁺)ATPase). The movements of the cations in each direction and the hydrolysis of the MgATP are coupled obligatorily so that the free energy from the hydrolysis of ATP is converted into electrochemical gradients of the cations. The similarity of these three chemical reactions is quite striking.

No other enzymes which reside in the extramitochondrial membranes of animal cells and which can convert metabolic energy directly into the work required to move molecules against a concentration gradient have been described. In addition, every other known example of net extrusion or accumulation of any substance against its concentration gradient across an animal cell plasma membrane involves the coupling of that movement to the electrochemical gradient of sodium created by $(Na^+ + K^+)ATP$ ase. In other words, the three chemical equilibria shown above describe all known examples of active transport in animal cells. Therefore, when active transport is used as a term here, it will refer only to the reactions catalysed by $(Na^+ + K^+)ATP$ ase, Ca^{2+} -ATPase and $(H^+ + K^+)ATP$ ase.

These enzymes, as well as a membrane-bound ATPase in fungi responsible for active proton extrusion⁷, are very closely related to each other. They each contain a large polypeptide chain whose apparent length, from SDS-polyacrylamide gel analysis, lies between 900 and 1,200 residues^{1-4,8}. In each case

this polypeptide is the phosphorylated intermediate associated with catalysis^{3,9-12}. Additional similarities have been noted between Ca2+ ATPase of the sarcoplasmic reticulum and (Na++ K⁺)ATPase of the plasma membrane. Both proteins have an identical sequence around the aspartic acid residue which is phosphorylated during turnover¹³, and both have membraneaffiliated regions distributed throughout the catalytic subunit¹⁴⁻¹⁶. Finally, the phosphorylated aspartic acid in both proteins is located in the same region of the catalytic subunit, 200–400 residues from the amino terminus^{16,17}. Although the other enzymes which catalyse active transport, $(H^+ + K^+) \overline{ATP}$ as and the fungal H⁺-ATPase, have yet to be studied as carefully, it is reasonable to assume that they will share these similarities. These correlations suggest that all the enzymes which catalyse active transport share a common ancestor. Thus, conclusions drawn from any one of these enzymes probably apply to all of them. In particular, they all must have very similar kinetic mechanisms which proceed through analogous intermediate steps and all must have equivalent tertiary and quaternary structures, positions within the bilayer and cation channels.

It is unclear how these enzymes move cations across the membrane or how they couple the movement of the cations to ATP hydrolysis. The answers to these questions are likely to involve molecular explanations of at least two conformations which these enzymes can assume on the one hand, and on the other, of the minimum unit necessary for enzymatic function.

Kinetic mechanism

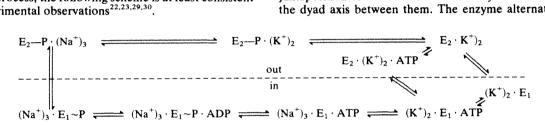

Various aspects of the sequence of kinetic steps through which (Na^++K^+) ATPase passes during its turnover have been examined both in membrane fragments and in the ATP-dependent, ouabain-inhibited, active cation fluxes of sealed systems. (Na^++K^+) ATPase can be covalently phosphorylated on an asparate residue by the γ phosphate of MgATP¹⁸; the phosphorylated intermediate is formed in the presence of sodium but hydrolysed in the presence of potassium¹⁹. This acyl phosphate has rates of formation and decay which are rapid enough for it to be an intermediate in the kinetic sequence of the reaction of the enzyme. When the rate of its forward decomposition is constant, the rate of overall turnover is directly proportional to its steady-state concentration²⁰. These experiments clearly establish that the enzyme is phosphorylated and dephosphorylated each time it turns over, and they divide active transport into two distinct steps.

Although the distinction between phosphorylated and unphosphorylated enzyme is a simple one involving the presence or absence of a covalent bond, there also seem to be at least two unique conformations of the native enzyme, the definitions of which are rather more ambiguous. Nevertheless, it is believed that the conformational changes which interconvert these states are more fundamental than phosphorylation and are responsible for the actual movement of the respective cations from one side of the membrane to the other. The two conformations, designated E_1 and E_2 , differ in their affinity for $ATP^{21,22}$, their intrinsic fluorescence spectra²³, susceptibility to trypsin^{17,24,25} and the response of their phosphorylated intermediates to ADP and K^+ (ref. 26). Transitions between E_1 and E_2 are detected by changes in any one of these properties. Both N-ethylmaleimide alkylation²⁷ and oligomycin²⁸ prevent these transitions.

Although there is still extensive disagreement about the details of the process, the following scheme is at least consistent with the experimental observations 22,23,29,30.

multimer, which has evolved under all these constraints, is a dimer whose dyad axis runs through the membrane. Furthermore, the only significant channels which pass through the centre of protein molecules lie between subunits and are often found centred on axes of symmetry. The true dyad of haemoglobin is the earliest and most striking example of this⁴². These consequences, which result when the rules that govern the symmetry of oligomeric proteins⁴¹ are applied to the two-dimensional environment of the phospholipid bilayer^{36,43}, have recently been reviewed by Klingenberg⁴⁴.

It is known that active transport of sodium and potassium through membranes does not involve the rotational or translational diffusion of $(Na^+ + K^+)ATP$ ase across the membrane⁴⁵. Thus it has been proposed that the enzyme spans the plasma membrane³⁶ and forms a channel across it through which the cations pass. In this scheme the pathway for the cations lies through the centre of the enzyme molecule, and is formed by the juxtaposition of two subunits of the enzyme and located along the dyad axis between them. The enzyme alternates between

Some of the steps in this scheme are proposed as the result of kinetic inference, but most have been directly observed and rate constants or equilibrium constants have been assigned to them. In normal circumstances the cycle operates in the clockwise direction, extruding sodium and accumulating potassium. Kinetic experiments indicate that the transition from $E_1 \sim P$ to E₂-P requires sodium to be bound to the enzyme, whereas the transition between E₂ and E₁ requires potassium. This suggests that E₁ is the inward-facing form of the enzyme which normally releases potassium as a product and receives sodium as a substrate, and E2 the outward-facing form which releases sodium as a product and receives potassium as a substrate. Therefore, it is during the transition between these two forms that the cations traverse the plasma membrane. Kinetic experiments with Ca2+-ATPase^{31,32} and (H⁺+K⁺)ATPase³³ have been interpreted in terms of a mechanism completely included within the more detailed mechanism which is currently available for (Na++ K⁺)ATPase. No counter ion, however, has been identified which would have the same role in Ca²⁺-ATPase that K⁺ does in the mechanism of $(Na^+ + K^+)ATPase$ and $(H^+ + K^+)ATPase$. It should be emphasized that this mechanism is able to explain² the negative cooperativity displayed in the MgATP kinetics of Ca^{2+} -ATPase³⁴, $(H^+ + K^+)ATPase^{33}$ and $(Na^+ + K^+)ATPase^{35}$ without any need to postulate half-of-sites behaviour or intersubunit interactions.

Molecular structure

While these kinetic observations were being accumulated, another series of experiments were being done to provide evidence for a particular structural explanation of the transition between E₁ and E₂. These experiments evolved from the following theoretical argument³⁶. In a lipid bilayer all protein molecules of the same sequence are inserted so that they point in the same direction^{37,38}. As the same area on the surface of each molecule, which is defined by a preponderance of aliphatic amino acid side chains³⁹, interacts with the boundary lipid⁴⁰, all folded polypeptide chains of the same sequence float at the same depth. With few exceptions, when two or more identical polypeptide chains combine to form a multi-subunit complex, they form a closed structure by arranging themselves about a rotational axis of symmetry⁴¹. In the membrane, this axis of symmetry is necessarily normal to the plane of the bilayer. The simplest arrangement of subunits in a membrane-bound

two conformational states, E_1 and E_2 , during turnover. These conformations differ from each other primarily in small structural alterations in the geometry of the channel; E_1 provides access to the cation compartment from the inside of the cell, E_2 from the outside. During the conformational changes which lead to net transport, each cation remains in the compartment and then departs into the medium on the side of the plasma membrane opposite to that from which it originally came. This hypothesis for the mechanism of $(Na^+ + K^+)ATPase^{36}$, and by analogy for the other enzymes catalysing active transport, was adapted from a model originally discussed by Jardetzky⁴⁶, generalized to other systems by Singer⁴⁷, and described in Klingenberg's article⁴⁴.

This proposal is only barely consistent with what is known about the structure of (Na++K+)ATPase. Purified canine renal (Na⁺+K⁺)ATPase contains two polypeptide chains, one a larger (α , molecular weight (MW) $120,000 \pm 10,000$), relatively hydrophobic protein, and the other a smaller (β , MW 55,000 \pm 5,000) sialoglycoprotein^{43,48}. It is the larger polypeptide which is the sibling of the polypeptides from Ca²⁺ ATPase and (H⁺+ K⁺)ATPase and it is generally assumed that this chain has the catalytic role. Both these polypeptides, however, are part of a specific complex⁴³ because they can be cross-linked to form a unique $\alpha\beta$ heterodimer^{48,49}. The two chains are present in the native enzyme in equimolar ratio⁴³ so that the minimum asymmetric unit is $\alpha\beta$. In certain conditions, it is possible to form a unique, covalently cross-linked α_2 dimer^{36,49,50}. Discrete complexes with apparent molecular weights of 380,000 (ref. 51) and 280,000 (ref. 52) and which are capable of regaining activity have been produced by detergent treatment. Electron micrographs have also been interpreted as indicating that the native enzyme is a multimer of $\alpha\beta$ units⁵³. The presently accepted, although far from proved, structure of native (Na+ K+)ATPase is shown in Fig. 1. If this structure is accurate, then Ca2+ ATPase and $(H^+ + K^+)ATP$ as must have the same appearance except that the β chain would be missing.

Klingenberg⁴⁴ has proposed that the present experimental evidence is sufficient to conclude that the structure shown in Fig. 1 is correct for (Na⁺+K⁺)ATPase. In addition, he assembles other experimental results which suggest that oligomeric structures are common in membrane-bound proteins. Although this may be true, it is far from from proved, and it would be useful here to review briefly the serious shortcomings of the procedures which were used to reach these conclusions.

Oligomeric associations

In the case of covalent cross-linking, the geometry of the membrane itself confuses the result. In all membranes or membrane fragments, the distances between neighbouring protein molecules are much shorter than the distances between molecules in even the most concentrated isotropic solutions of soluble proteins. As a result, collisions between unassociated molecules are much more frequent, increasing the likelihood of artefactual cross-linking. Although the overall cross-linking reactions are often pseudo-first order in their kinetics³⁶, this is consistent with either a preexisting complex or an initial ratelimiting covalent reaction followed by a very rapid collision of monomers. An additional problem caused by the two-dimensional properties of the bilayer is that on every monomer of a certain sequence, each of the specific amino acid residues which are the targets for a given cross-linking reagent will lie at the same distance from the centre of the bilayer as its twin on another monomer. When bis-functional reagents are used, this fact greatly increases the likelihood that the twins will be coupled on collision. Once a covalent, symmetrical pair is formed, however, from two previously unacquainted monomers, neither has the reactive position available for further polymerization and a unique covalent dimer will be observed with no evidence of higher oligomers. A striking example of this principle is the adventitious dimer of acetylcholine receptors which is found in preparations made in the absence of reducing reagents but which serves no biological purpose⁵⁴. Finally, cross-linking of membrane-bound proteins is rendered more ambiguous by the presence of the randomly oriented clusters of proteins often seen in electron micrographs⁵³.

The oligomeric assemblies of membrane-bound proteins which have been observed in the ultracentrifuge when these molecules are dissolved in various detergents are also cited⁴⁴ as evidence for the existence of similar, native complexes. It is not the case, however, that only one, unambiguous complex is always observed under these circumstances. Stable tetramers, dimers and monomers of Ca2+-ATPase have been separated and identified55. (Na++K+)ATPase, on the other hand, is supposed to exist as a dimer in detergent solution, compatible with the fantasy shown in Fig. 1. However the molecular weights, determined for this presumably discrete complex by ultracentrifugation in two separate laboratories^{51,52}, differ by 30% from each other. Furthermore, in neither case did the protein show (Na++K+)ATPase activity when dissolved in the concentration of detergent required to disperse it. Finally, the very substantial corrections which are necessary to account for the effects of bound detergent, carbohydrate and lipid on the hydrodynamic properties of the particle⁵¹, although theoretically pleasing, have yet to be independently verified. The cautious reader should note the errors made with aldolase⁵⁶ and aspartate transcarbamoylase⁵⁷ with the assistance of an even less complicated theoretical development in much simpler circumstances.

A clear indication of the uncertainty of the present position is that Klingenberg⁴⁴ has concluded, from experimental results of the type just discussed, that $(Na^+ + K^+)ATP$ ase is a dimer of asymmetric units, whereas $Ca^{2+}-ATP$ ase is a tetramer. If this

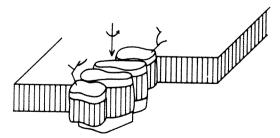

Fig. 1 Drawing of the imagined molecular structure of $(Na^+ + K^+)ATP$ ase. The subunits are drawn so that their volumes correspond to molecular weights of 120,000 and 55,000 using as a scale the width of the bilayer (4.0 nm).

were true, $(Na^+ + K^+)ATP$ ase would have a two-fold symmetry axis and Ca^{2^+} -ATPase, a four-fold one. As it is impossible to evolve a protein with a four-fold axis from one with a two-fold axis, or vice versa, the common ancestor of these proteins would have been a monomer. If this were the case, the oligomeric structures of these proteins would be irrelevant to the process of active transport. A more likely resolution of this confusion, however, is that both $(Na^+ + K^+)ATP$ ase and $Ca^{2^+}ATP$ ase have the same oligomeric structure but the true aggregation state of neither has been established.

Half-of-sites behaviour

Unfortunately, the theoretical proposals for the mechanism of active transport and the experiments which investigated the quaternary structures of membrane-bound proteins were being published at a time when enthusiasm for half-of-sites mechanisms of enzyme catalysis had reached its peak⁵⁸. It was immediately apparent that active transport was a strong candidate for half-of-sites behaviour, and many results appeared which supported the possibility. There are several ligands which bind to (Na++K+)ATPase: ouabain, vanadate, ATP and the phosphate of the covalent intermediate. Whenever comparisons are made with the same enzyme preparation, the molar concentrations of each of these sites are the same 59-63. As such, these ligands define the concentration of functional (Na*+ K+)ATPase units or active sites. There have been many estimates of the grams of protein per mol of sites in purified (Na++K+)ATPase—these usually lie between 220,000 and 280,000 g per mol of sites⁵⁹⁻⁶³. If one decides, on the basis of electrophoretic mobility, that the molecular weights of α and β are 90,000 and 35,000, respectively, it can be concluded that there is about one site for the ligands per $(\alpha \beta)_2$ or 'half-of-sites'.

This conclusion had three major weaknesses. Most of the protein concentrations were based on the Lowry method which does not yield accurate, absolute estimates of protein concentration unless extinction coefficients are independently determined⁶⁴. Second, any estimate of grams per mol of sites necessarily represents only an upper limit of the true number because some inactive protein is always present. Therefore, the lower numbers are the more important estimates. Finally, the molecular weights quoted for the chains are based only on gel electrophoresis, which gives minimum estimates of the true molecular weight of a hydrophobic protein⁶⁵. It has been pointed out that SDS-polyacrylamide gel electrophoresis underestimates the molecular weight of the subunit of Ca2+-ATPase as a determination of this quantity by sedimentation equilibrium indicates that the true molecular weight of this polypeptide chain is 120,000 (ref. 66).

New estimates of ouabain and ATP site concentrations for $(Na^+ + K^+)$ ATPase, based on protein determination by quantitative amino acid analysis, yield values of $180,000 \pm 20,000$ g per mol of sites^{22,67}. Similar values have also been obtained recently for the concentration of phosphorylation sites⁶⁸. Finally, it has been established that there are 0.8-0.9 phosphorylation sites^{10,69} and ATP-binding sites⁶⁹ present on each polypeptide chain in purified Ca^{2+} -ATPase. Clearly there is sufficient reason to doubt that active transport enzymes ever display half-of-sites behaviour.

In this context, it is illuminating to consider the present state of the half-of-sites or negative cooperativity problem in general. With the exception of hexokinase⁷⁰, which for symmetry reasons is irrelevant to the problem of membrane-bound proteins, the number of established cases of half-of-sites behaviour is rapidly dwindling. There are many reasons why mistakes were made, even with soluble proteins, and each is more likely to occur when a membrane-bound enzyme is examined. The most common problem is heterogeneity of enzyme due to the presence of contaminating, inactive protein⁷¹ of partially denatured enzyme of lower affinity^{72,73} or another protein which alters the properties of some of the enzyme⁷⁴. It is remarkable how such situations which should lead to various degrees of heterogeneous behaviour always produce half-of-sites behaviour; the concen-

Fig. 2 Hypothetical equilibrium between two monomers and a dimer of (Na++K+)ATPase asymmetric units dissolved in detergent. The detergent replaces the bilayer as a collar around the protein.

tration of sites is always half that expected. A corollary of these considerations would be the consequences which would result if some of the enzyme had been completely denatured during the detergent treatments necessary to isolate membrane-bound proteins. The partial or complete demise of an enzyme almost never alters its behaviour on polyacrylamide gels and would pass unnoticed in the ultracentrifuge. Another problem encountered with membrane-bound proteins is the presence of vesicles and multibilayers which prevent access of ligands to their otherwise normal sites. For example, the concentration of cardiac glycoside sites on (Na++K+)ATPase increases 1.6-fold when a membrane-bound, vesicular preparation is dissolved in detergent⁶⁷ even though the polyacrylamide gels of the two preparations are indistinguishable.

Finally, the shortcomings of the analytical procedures themselves must be considered. Any practising protein chemist realizes that the determination of the actual protein concentration in an experimental sample is extremely difficult²². A direct approach to the determination of the concentration of sites in a given preparation is often plagued by the problems of unstable intermediates, loss of protein, or large concentrations of unbound ligand-difficulties which can be overcome, however, by using more imaginative procedures⁷⁵. Often, the actual molecular weight of the subunits is doubtful. This quantity can only be established unambiguously from the sequence 76, but few sequences of membrane-bound proteins are available. which are show that SDS-polyacrylamide gel electrophoresis significantly underestimates their true polypeptide length^{τ}

Almost all these difficulties result in an apparent decrease in the concentration of sites relative to the concentration of the polypeptide and may have contributed to the erroneous conclusion that half-of-sites behaviour is shown by active transport enzymes.

Present uncertainty

Thus it is unknown whether the boundary between two α subunits is involved in the process of active transport. The hyperbolic, non-interacting binding curves which are generally observed for the various ligands imply that the sites on each chain are well separated from each other and certainly not located within the same active site. Although dispersed forms of (Na++K+)ATPase and Ca2+-ATPase which seem to be multimeric have been identified, their existence does not necessarily imply that such arrangements are critical for function, something half-of-sites could have settled. Reports which propose that Ca2+-ATPase can function as a monomer further complicate the issue⁷⁸⁻⁸⁰. If this were true, it would eliminate the hypothesis outlined above, as well as any consideration of 'half-of-sites', in the case of active transport. There are several distinct difficulties, however, with these experiments. First, estimations of the aggregation state of the enzyme were based only on hydrodynamic parameters which are difficult to interpret in systems containing protein, lipid and detergent. Furthermore, no attempt was made to determine the quaternary structure of the enzyme at the same time that turnover was being observed. If an equilibrium such as the one depicted in Fig. 2 can occur, then the conditions of the enzyme assay may promote dimerization and reactivation even though an inactive monomer is present in the ultracentrifuge. In conclusion, it is unknown whether the functional unit of an active transport protein is monomeric or dimeric, and if a dimer is involved whether it can participate in the way described above and yet not display half-of-sites behaviour.

Detecting CO₂-induced climatic change

T. M. L. Wigley & P. D. Jones

Climatic Research Unit, University of East Anglia, Norwich NR4 7TJ, UK

Although it is widely believed that increasing atmospheric CO_2 levels will cause noticeable global warming, the effects are not yet detectable, possibly because of the 'noise' of natural climatic variability. An examination of the spatial and seasonal distribution of signal-to-noise ratio shows that the highest values occur in summer and annual mean surface temperatures averaged over the Northern Hemisphere or over mid-latitudes. The spatial and seasonal characteristics of the early twentieth century warming were similar to those expected from increasing CO_2 based on an equilibrium response model. This similarity may hinder the early detection of CO_2 effects on climate.

OVER the past $100\,\mathrm{yr}$ there has been a steady increase of atmospheric carbon dioxide levels¹ with the concentration rising from $\sim 315\,\mathrm{p.p.m.}$ in $1958\,\mathrm{to}\,338\,\mathrm{p.p.m.}$ in $1980^{2.3}$. Most of this increase can be attributed to the ever-increasing use of fossil fuels. Carbon budget studies indicate that atmospheric CO_2 may reach $600\,\mathrm{p.p.m.}$, approximately double the pre-industrial level, some time between AD 2030 and $2080^{4.5}$. A doubling of CO_2 levels may well cause a major climatic change: however, the increase so far is probably too small for attendant climatic change to be detected above the 'noise' of natural climatic variability $^{6.7}$.

It has therefore been suggested⁸ that attention should be directed to the identification of a 'precursor signal' of the effects of CO₂ on climate. This requires a knowledge of the signal and a knowledge of the noise. The signal can be estimated only by numerical modelling experiments; the noise, a result of the considerable natural variability of climate, can be estimated using recent instrumental data. Simple radiative-convective energy balance models9 indicate that a doubling of CO2 could produce an increase in global mean annual surface temperature of 2-3 °C. More complex models 10-12 give information about the spatial and seasonal patterns of climatic change, but there is still considerable uncertainty in these model simulations. Nevertheless, for any given modelled signal we can estimate, using recent data, the corresponding noise and so calculate a signal-to-noise ratio. The best climate parameters to monitor are those with the highest signal-to-noise ratio. These are not necessarily those with the highest signal.

Signal-to-noise ratio

One approach is to look for significant changes in the mean values of particular climate parameters. Climatic noise manifests itself through uncertainties in the means, which in turn can be quantified by the statistical confidence limits for the sample mean (\bar{X}) as an estimate of the population mean. For a sample of size N(yr) with variance $\hat{s}_N^2 (\equiv \{\sum_{i=1}^N (X_i - \bar{X})^2\}/N - 1)$, the confidence limits' range, which is proportional to \hat{s}_N/\sqrt{N} , decreases roughly as $1/\sqrt{N}$. Averaging over longer time periods gives a more confident estimate of the mean and reduces he noise level. However, the reduction in noise is not strictly proportional to $1/\sqrt{N}$. Because most climate variables have a considerable amount of low-frequency variance, \hat{s}_N increases vith increasing sample size. Time-averaging reduces the noise, out not quite as rapidly as $1/\sqrt{N}$. To estimate the effect of ow-frequency variance, we suppose climate time series to ehave like first-order autoregressive processes. An additional actor

$$f(N, r) = \left\{ \frac{1+r}{1-r} - \frac{2r(1-r^N)}{N(1-r)^2} \right\}^{1/2}$$

where r is the lag-1 autocorrelation, appears, and the noise level can be defined as

$$\eta = \sqrt{2}(\hat{s}_N/\sqrt{N})f(N,r) \tag{1}$$

The signal-to-noise ratio is simply (signal)/ η . The $\sqrt{2}$ term arises because, in comparing two means, both will be subject to noise. As f(N, r) > 1, autocorrelation, or any type of enhanced low-frequency variance, effectively increases the noise level, and its presence makes the statistical detection of a signal more difficult.

Madden and Ramanathan⁷ have calculated the reduction in noise in seasonal and annual mean surface air temperatures at $60\,^{\circ}$ N due to time averaging, allowing for changes in \hat{s}_N . Their analysis suggests that, in the absence of other compensating effects, and ignoring lag effects due to the thermal inertia of the oceans, the CO_2 signal should be detectable either now or by about AD 2000, depending on the assumed character of the signal. They conclude that the effects at $60\,^{\circ}$ N should be detectable most easily in summer.

Results for 60 °N need not apply to other latitudes, and it may well be that a higher signal-to-noise ratio obtains at some other latitude band. Furthermore, because spatial averaging reduces the noise level in most climate parameters, averages over wider latitudinal ranges may increase the signal-to-noise ratio. We test these possibilities in this article.

Madden and Ramanathan used the results of Manabe and Wetherald¹⁰ and Ramanathan et al.¹³ to estimate the signal. In the latter work, the maximum signal is in high latitudes and in late spring-early summer. Here we use the general circulation model results of Manabe and Stouffer¹² in which the signal is greatest at high latitudes and in late autumn to winter. Although the signal should certainly differ from season to season, there is some doubt about the seasonal distribution⁷.

For our noise data we use gridded (5° latitude by 10° longitude) monthly surface air temperature data for the Northern Hemisphere over the period 1941–80 from ref. 14. The basic data are from World Weather Records, updated by NOAA in Monthly Climatic Data for the World, and supplemented with data from various National Meteorological Services, published records, and from the CLIMAT network. The number of individual stations varies from ~ 800 to 1,300. Data coverage becomes less complete as one moves back from 1940. Because of the sparsity of meteorological stations in ocean areas, the data grid has quite large gaps over the oceans. We have therefore used the land-area signal given by Manabe and Stouffer (their Fig. 16c) to calculate signal-to-noise ratios.

Spatial distribution of signal-to-noise ratio

In Fig. 1 we show the signal-to-noise ratio (\$N) as a function of latitude and month which is defined as

$$SN = \frac{1}{2}\Delta T_{MS}/\eta \tag{2}$$

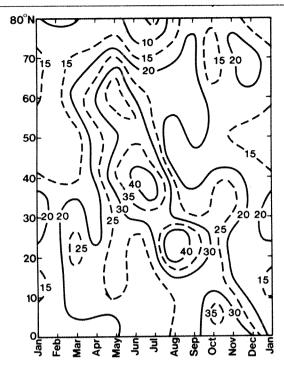

Fig. 1 Signal-to-noise ratio for predicted CO_2 -induced changes in surface air temperature as a function of latitude and month. The signal is based on the numerical modelling results of Manabe and Stouffer¹². The noise has been calculated from grid-point surface temperature data¹⁴: the value for month j at latitude L is the areally weighted average of grid points at L-5, L and L+5, and the noise level is proportional the standard deviation of month-j values over the period 1941–80, corrected for autocorrelation effects.

where η is given by equation (1), and $\Delta T_{\rm MS}$ is the temperature increase for a quadrupling of atmospheric CO₂ (the factor 1/2 arises because ΔT is approximately proportional to $\ln q$ where $q = {\rm CO_2/CO_2^0}$ (ref. 7)). We have allowed for the effect of low-frequency variance on time-averaging by including the term f(N,r). f(N,r) is generally near 1 for our data, but ranges up to a maximum near 2. Its inclusion makes little qualitative difference to our results. Although our noise levels have been calculated using the period 1941-80 (N=40), we have examined other time periods (and different values of N) and obtained very similar results. A value of SN ≥ 1.7 corresponds to a statistically significant ΔT at the 0.05 level. The temperature changes corresponding to a doubling of CO₂ are highly significant for all months and all latitudes relative to the noise level.

Figure 1 shows that the most likely season and latitude zone in which to detect the effects of CO_2 is during the summer months in middle latitudes; in spite of the fact that the assumed maximum signal is in winter in high latitudes. The importance of summer in detecting CO_2 effects is in accord with Madden and Ramanathan⁷, but our results suggest that the signal-to-noise ratio around 40 °N is higher than at 60 °N.

Monthly values of zonally averaged temperatures may not give the highest values of SN. Averaging into seasons and over the whole year reduces the variance of climate parameters, and a further variance reduction can be achieved by spatial averaging. We therefore examined seasonal and annual data for four different regions, a low-latitude zone (5° S-25° N inclusive), a mid-latitude zone (25°-55° N), a high-latitude zone (55°-85° N) and the whole Northern Hemisphere (0-85° N). SN values, defined as above, are given in Table 1. From these results, and similar analyses of different time periods (not shown here), the highest signal-to-noise ratios appear to be for summer midlatitudes, spring and summer Northern Hemisphere averages, annual mid-latitudes and annual Northern Hemisphere averages. Models with a different seasonal distribution of signal (see ref. 13) would imply even stronger signal-to-noise ratios in summer.

Recent changes in Northern Hemisphere and mid-latitude, summer and annual average surface temperatures are shown in Fig. 2. Some of the short-term variability has been smoothed out by using a 1-2-1 binomial filter, but the noisiness of the record is apparent. In neither of the summer curves is there any apparent trend (in either direction) since the mid-1960s. A slight upward trend is noticeable in the annual curves after 1972, but more pronounced and longer-lasting trends have occurred before, noticeably before 1940. We therefore examined this early warming period more closely.

Comparison with an earlier warming period

Figure 2 shows the strong warming trend in Northern Hemisphere and mid-latitude, summer and annual average temperatures between 1910 and 1938. If we compare the coldest and warmest 20-yr periods this century (1901–20 and 1934–53 respectively), then all seasons and latitude bands show a warming. Statistically, the most significant changes occurred in Northern Hemisphere averages for spring, summer, autumn and annual means, and in mid-latitude averages for summer and annual means, in striking accord with the latitude zones and seasons for which the CO₂ signal-to-noise ratio is highest (Table 1).

Although we can be reasonably sure that the early twentieth century warming was not due to increasing CO2, it is instructive to examine this possibility more closely. Two approaches may be used to test the hypothesis that CO₂ was a causal factor; the magnitude of warming can be compared with that expected from the known increase in atmospheric CO2, or the spatial and seasonal patterns of warming can be compared with those expected on the basis of CO₂ modelling experiments. The latter comparison is shown in Fig. 3 where the CO₂ signal¹² is plotted against the temperature change between 1901-20 and 1934-53 using the same seasonal and spatial grouping as before. The comparison is sufficiently good that is could be taken to support CO₂ as a cause for the early twentieth century warming. There are some interesting differences, however. Compared with the annual Northern Hemisphere temperature change, the observed low-latitude changes were too low, especially in summer. In mid-latitudes the seasonal character of the observed changes (winter minimum, summer maximum) contrasts sharply with that expected on the basis of Manabe and Stouffer's model, but

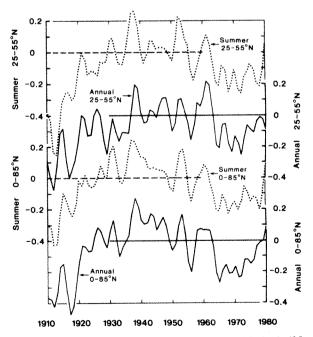

Fig. 2 Variations in Northern Hemisphere and mid-latitude (25-55° N) summer and annual average temperatures over the past 70 yr from ref. 14. The values are anomalies relative to the 1946-60 mean and have been filtered using a three-term binomial filter (except for the 1980 value).

accords better with Ramanathan et al.¹³. Given our lack of understanding of the details of both natural and CO₂-induced climatic change, these exceptions alone are probably insufficient to reject CO₂ as a possible cause of the early twentieth century warming.

However, the warming between 1901-20 and 1934-53 is, based on the most recent numerical model results, much larger than would be expected to result from the small increase in atmospheric CO₂ which occurred over this period. Additionally, between about 1940 and 1970 there was a significant cooling (Fig. 2) and this is incompatible with the CO₂ hypothesis.

The early twentieth century warming is a low-frequency component of the noise which acts to obscure any influence of increasing atmospheric CO₂ (in so far as any climatic change which is not attributable to CO₂ can be considered as noise). Because we have information about only one manifestation of this low-frequency component, we know nothing about its statistical properties. Nevertheless, this single example illustrates the similarity between natural and predicted CO₂-induced temperature changes; a similarity which might imply that analysis of spatial and/or seasonal details of future variations in surface temperature will be of little help in distinguishing natural changes from the effects of CO₂.

A second difficulty in detecting CO₂ effects arises because of lags in the response to increasing CO2 which result from thermal inertia associated with oceanic mixing¹⁵. Most models used in studying possible CO₂ effects (including that of Manabe and Stouffer¹²) have considered the equilibrium response to a stepfunction increase in CO₂. Transient response models¹⁵ indicate that oceanic influences might cause the climate response to lag 5-20 yr behind the CO₂ forcing. Such a lag, in itself, is a significant factor in determining when the effects of CO2 might first be detected. However, an equally important result is that the spatial pattern of the transient response may differ considerably from that expected on the basis of equilibrium models¹⁵. We have shown that the character of natural lowfrequency changes in surface temperature can be similar to the equilibrium CO₂ response. If transient response patterns do differ from equilibrium response patterns, this may make it easier to distinguish CO₂ effects from natural changes in climate.

Conclusions

We have examined the signal-to-noise ratio for surface temperature averaged over periods of 1 month to 1 yr and over latitude zones of widths from about 15° to 85°. The quantitative details of our results, especially those in Fig. 1, are model dependent. Our general conclusions are, however, relatively insensitive to the choice of the model used to define the CO₂ signal, because they depend strongly on the spatial and seasonal distribution of the natural variability of surface temperatures. For example, our conclusion that signal-to-noise ratio is highest for mid-latitude or Northern Hemisphere summer or annual means arises primarily because of the relatively low natural variability of summer temperatures. We can also conclude that the signal-to-noise ratio in low latitudes is of comparable magnitude to that in high latitudes (see Table 1), primarily

Table 1 Signal-to-noise ratio for different latitude bands and seasons

Latitude range	Winter	Spring	Summer	Autumn	Annual
Low (5° S-25° N)	23 (1.6)	28 (1.7)	36 (1.6)	36 (1.8)	31 (1.7)
Mid (25° N-55° N)	26 (2.7)	36 (2.4)	49 (2.2)	40 (2.4)	53 (2.4)
High (55° N-85° N)	23 (4.6)	31 (4.1)	25 (2.0)	28 (3.5)	33 (3.5)
Northern Hemisphere (0-85° N)	32 (2.6)	44 (2.4)	43 (1.9)	35 (2.4)	44 (2.3)

The signal (° C) corresponding to a doubling of CO_2 (that is $\frac{1}{2}\Delta T_{MS}$) is given in parentheses; based on Manabe and Stouffer 12.

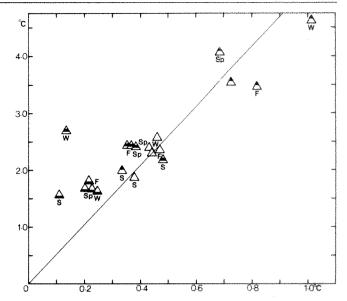

Fig. 3 Comparison of observed temperature changes between 1901–20 and 1934–53 with changes expected to result from increasing atmospheric CO_2 levels. The abscissa is the observed temperature change and the ordinate is the CO_2 signal for a doubling of CO_2 based on the land area results of Manabe and Stouffer 12. Different latitude bands are distinguished by the position of the band in the triangle. \triangle , Hemispheric averages. Seasons: W, winter; Sp, spring; S, summer; F, autumn or fall; no letter, annual average.

because of the low variability of low-latitude surface temperatures. This conclusion would only be invalidated if the ice-albedo feedback at high latitudes were considerably underestimated by currently available climate models: this is unlikely¹⁵. The uncertainty in the spatial patterns of climate response to increasing atmospheric CO₂ places considerable emphasis on monitoring large-scale averages for precursor signals of the effects of CO₂.

Because of the demonstrated similarity between observed natural changes in surface temperature and the changes predicted by Manabe and Stouffer's equilibrium model¹², it is important to investigate in more detail the differences in response between equilibrium and transient response models. If the differences are large, this would cast same doubt on the value of both equilibrium model results¹² and instrumental analogues¹⁶ in generating spatially detailed scenarios for a high-CO₂ warmer world. If the differences are small, the opposite conclusion could be drawn.

The change in surface temperature between 1901-20 and 1934-53 was similar in magnitude to that expected to result from a CO₂ increase of ~14% based on Manabe and Stouffer's model¹². Between 1970 and 1980 atmospheric CO₂ concentration increased by ~4%. A further 10% increase will almost certainly occur before the year 2000, probably by 1990. We might, therefore, anticipate changes in climate of a similar magnitude to those experienced in the first half of this century to occur over the next 10-20 yr. As most of the early twentieth century warming occurred between the late 1910s and the late 1930s (Fig. 2), the rate of future CO2 induced changes this century is unlikely to be faster than natural changes which we have recently experienced. If current model simulations are correct, then the rate of change of surface semperatures over the next 20 yr is, therefore, not likely to be useful in distinguishing CO₂ effects from natural climatic change.

Because of difficulties in using surface temperature data to detect the effects of increasing atmospheric CO₂, it is important to look at other climate parameters. There is a strong statistical and causal link between circulation changes and changes in surface temperature ¹⁷, so that surface climate variables other than temperature may not help significantly in trying to distinguish CO₂-induced changes from natural changes in climate.

Detailed spatial studies are hampered by the uncertainties in the spatial patterns of CO₂ effects. The predicted cooling of stratospheric temperatures might be useful, but our knowledge of the natural variability of stratospheric temperatures is meagre. Furthermore, other anthropogenic effects might also cause stratospheric cooling¹⁸. The same problems apply to monitoring changes in lapse rate¹⁹. An interesting possibility might be to monitor satellite radiation budget data as suggested by Madden and Ramanathan⁷.

The noise level in climate data may be reduced by eliminating variations with known causes. For example, the Southern Oscillation^{20,21} accounts for a significant part of the climate variance in some parts of the world, and this component might usefully be factored out by regression techniques. Alternatively, if there were accurate measurements of atmospheric turbidity and/or solar variability to which aspects of climatic change could be unequivocally ascribed, then the effects of these parameters

could be removed, either by using numerical models or, less satisfactorily, by using empirically-based statistical relationships. Further improvements in numerical models and in our understanding of the causes of recent climatic change are required before this approach can give convincing results.

The effects of CO₂ may not be detectable until around the turn of the century. By this time, atmospheric CO₂ concentration will probably have become sufficiently high (and we will be committed to further increases) that a climatic change significantly larger than any which has occurred in the past century could be unavoidable. To avert such a change it is possible that decisions will have to be made (for example, to reduce anthropogenic CO₂ emissions) some time before unequivocal observational 'proof' of the effects of CO2 on climate is available.

Long-period geomagnetic secular variations since 12,000 yr BP

K. M. Creer

Department of Geophysics, University of Edinburgh, Mayfield Road, Edinburgh EH9 3JZ, UK

A comparison of secular variation records of the geomagnetic field inclination obtained from palaeomagnetic studies of European and North American post-Glacial and late-Glacial sediments suggests that geomagnetic westward drift has persisted through the past 12,000 yr. Between 12,000 and 2,500 yr BP the overall average drift rate was between 0.14 and 0.16 deg yr^{-1} . At $\sim 2,500 \text{ yr BP}$ it is tentatively suggested that the drift rate increased and rose to a maximum of nearly 0.5 deg yr^{-1} before decreasing to historically observed values of $\sim 0.25 \text{ deg yr}^{-1}$.

OUR present knowledge of the spectrum and spacial characteristics of the geomagnetic field's longer period secular variations is derived from observatory magnetometer records which cover only the past two centuries, supplemented by the occasional magnetic compass and dip circle readings logged by ancient mariners1 thus limiting our understanding of how the field is generated. From these data, world maps contouring the various geomagnetic elements have been constructed for epochs through the past three to four centuries2-4 from spherical harmonic coefficients computed up to degree n = 4.

It is convenient to separate the observed field at any specific epoch into dipole and non-dipole components. The pattern of the non-dipole part of the field has been distributed around four positive and five negative foci throughout history. Geomagnetic secular variations are caused both by changes in intensity and orientation of the dipole and by westward drift and changes in intensity of the non-dipole part of the field. Through the past four centuries, some non-dipole foci have drifted to the west while others have stood still: some have maintained constant intensity while others have grown or decayed5.6

The geomagnetic field can be separated mathematically into drifting and standing parts⁷⁻⁹. The form of the drifting part of the vertical component of the non-dipole field is shown in Fig. 1 for the Northern and Southern Hemispheres using Yukutake and

Tachinaka's data8. Its contours exhibit an essentially quadrupolar symmetry: in each hemisphere there is one large positive and one large negative region, each of which contains its own individual structure which evolves with time. The mean rate of westward drift is ~ 0.25 deg yr⁻¹ which is similar to that determined by Barraclough² for the eccentric dipole into which the dipole and quadrupole parts of the field are sometimes combined. The direction of drift is not purely westward10; in particular, it seems that the general quadrupole has rotated clockwise at a rate of $0.25\pm \bar{0}.04$ deg yr⁻¹ during the present century¹¹ about a pole located near the Aleutian Islands rather than about the geographical pole.

The dipole component is not axial: its equatorial part has drifted to the west at an average rate of 0.29 deg yr⁻¹ since the sixteenth century10, though much slower drift rates have been obtained for epochs during the present century and have been explained by suggesting that the 'standing' part of the field actually undergoes a very slow eastward drift^{10,12}.

The lifetime of non-dipole sources was once thought to be as short as a few hundred years⁶, but recently substantially longer lifetimes of ~7,000 yr have been suggested¹⁰. For direct proof of such long lifetimes and of the persistency of westward drift we must look to archaeomagnetic and palaeomagnetic rather than observatory sources of data.

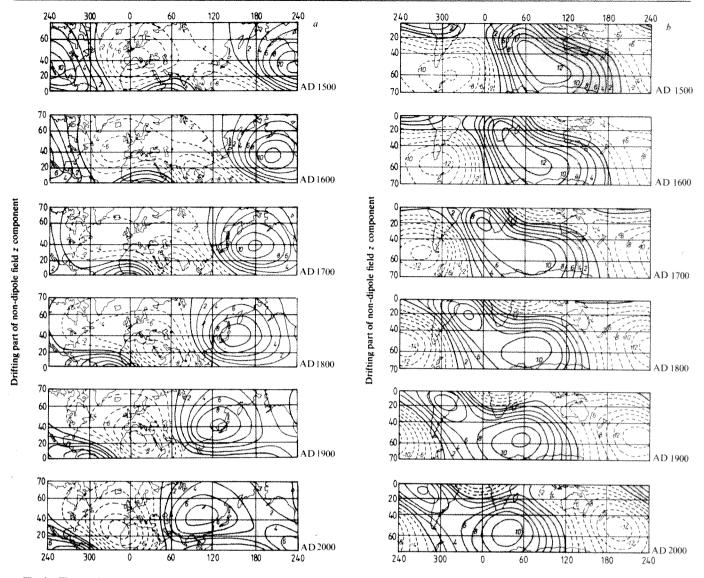

Fig. 1 The vertical component of the drifting part of the non-dipole field for six epochs from AD 1500 to AD 2000. a, Northern Hemisphere; b, Southern Hemisphere. Contour interval, 2,000 nT.

Thus, there are many gaps in our knowledge of the long term behaviour of the field during periods of settled polarity. The extended data sets becoming available from palaeomagnetic sources should help to resolve some of the outstanding problems.

Palaeomagnetic secular variation records

During the past decade significant developments have been made in techniques of taking high quality undisturbed cores of unconsolidated lake and marine sediments¹³ and it has become possible to measure their weak natural remanent magnetizations rapidly and accurately¹⁴. In favourable conditions of deposition this remanent magnetization has been found to carry a record of the secular variations of the direction of the ancient geomagnetic field at the site of deposition through the time the sediments were being accumulated. However, as might be expected, the quality of these natural records is much inferior to that we associate with instrumental records.

First, we must accept that the quality will be severely affected by any physical disturbance produced in the sediment, either naturally by slumping on the lake bottom due to, for example, to seismic activity or the action of turbidity currents, or mechanically during the coring process or during transport or during sub-sampling of cores. Another difficulty arises from the fact that corers often 'corkscrew' their way into the bottom sediments thus introducing a long wavelength trend and also discontinuities into the declination record. This is why more good quality inclination than declination records are available and why the present discussion is restricted to inclination secular variations.

Next, the natural remanent magnetization is not acquired instantaneously¹⁵: it is produced by a combination of different mechanisms such as post-depositional grain rotation, chemical changes and possibly bacterial action. Thus the recorded signal is always subjected to a variable degree of smoothing which explains why substantial variations in the amplitude of specific features identified along records from different places (see Figs 2 and 3) and even from different cores taken from the same lake are found.

Finally it is difficult to date recent sediments with the required degree of accuracy. Radiocarbon dates are often affected by the presence of recycled fossil carbon which may have been deposited into the sediment as fragments of fossil shell or plant remains ('old carbon' effect) or incorporated directly into organisms living at the time of deposition from calcium carbonate originating from pre-existing limestones dissolved in the lake water ('hard water' effect). Both these effects can produce radiocarbon ages which are too old by up to several thousand years so that we have to use indirect methods such as correlation of the 'palaeomagnetic' core with well-dated sections from the same locality using palynological or stratigraphical methods.

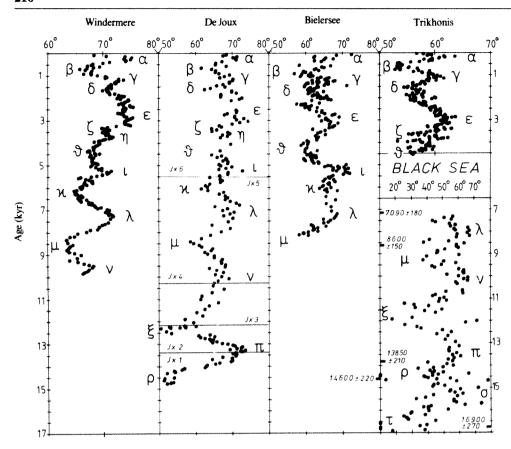

Fig. 2 Palaeomagnetic inclination logs for European sites. Time scale in uncalibrated radiocarbon years. Windermere 18 and Trikhonis 20 curves are each stacked from several individual core records. Pollen zone boundaries shown on Lac de Joux log 21. Radiocarbon ages shown along Black Sea log 22.

European post-Glacial and late-Glacial data

Limnomagnetic research started with Mackereth's study¹⁶ of post-Glacial sediments from Lake Windermere. Subsequent studies in UK (Lake Windermere, Loch Lomond, Lake Geirionydd) have produced a detailed and reproducible pattern of secular variations in inclination and declination 17,18 dated by over 30 radiocarbon age determinations. The characteristic features of the UK records, labelled $\alpha-\nu$, can also be recognized over a wide area of Europe from Poland¹⁹ to Greece²⁰. Records stacked from several cores from Lake Windermere $(54^{\circ}\text{N}\ 357^{\circ}\text{E})^{18}$ and from Lake Trikhonis $(39^{\circ}\text{N}\ 22^{\circ}\text{E})^{20}$ are shown in Fig. 2. A record from Lac de Joux $(47^{\circ}\text{N}\ 5^{\circ}\text{E})$ extending back to about 14,000 yr BP has been dated by correlation with the well established biostratigraphy for the Joux valley²¹. It exhibits features $\theta-\rho$ particularly well. The younger features $\alpha-\iota$ are exhibited more clearly for Switzerland in the Bielersee record, which as yet can be dated only by correlation of magnetic

	Table 1 Ages of inclination features

ρ	14,500*						

Ages are given in radiocarbon yr BP.

declination and inclination features with the calibrated Euopean records. Another inclination record extending from $\sim\!7,000$ yr BP to $\sim\!25,000$ yr BP (Fig. 2 goes to 17,000 yr BP) is provided by Black Sea core no.1474 (42°N 38°E) which was taken using a gravity piston corer. The time scale was constructed from seven radiocarbon age determinations²². Figure 2 thus shows the extent to which inclination secular variations can now be correlated across Europe back to $\sim\!15,000$ yr BP.

North American post-Glacial and late-Glacial data

Inclination secular variation records from Lakes St Croix and Kylen, Minnesota (46°N 267°E)²³ and the Thunder Bay part of Lake Superior (48°N 271°E)²⁴ are shown in Fig. 3. Characteristic features which correlate from site to site are labelled $\alpha-\pi$, although at this stage we should not identify them with the apparently similar features observed along the European records. At Lake St Croix parallel cores of organic rich gyttja were taken in sections by making successive 1.5-m drives using a piston corer. The cores were dated with eight radiocarbon age determinations²³ as indicated along the inclination record shown in Fig. 3. Thus the dating control is quite tight. At Lake Kylen, cores were taken using the same technique and dated by four radiocarbon age determinations. Note that there is a very large error of $\pm 1,500$ yr on the oldest age of 16,500 yr (ref. 22). Four cores were taken especially for palaeomagnetic study with an Alpine piston corer from Lake Superior²⁴. The age of the base of the post-Glacial was taken as 9,500 yr BP (ref. 25). Because sedimentation occurred in the Thunder Bay part of Lake Superior back to at least 11,000 yr BP (refs 25, 26), this age was taken as the age of the base of the core. The post-Glacial sediments were dated by nine radiocarbon age determinations some of which were affected by 'hard water' and 'old carbon' effects for which it is difficult to make a precise correction. The four oldest ages shown in Fig. 3 were accepted without correction and a 'zero-error' correction of 1,700 yr (following ref. 24) was applied to the three youngest ages. Thus this time scale is likely to be in error.

Though the pattern of variations provided by St Croix/Kylen record is not very well formed, the dating control is good. If the

ages of the labelled features obtained from this record are transferred to the rather well-formed Superior record a satisfactory inclination record for the Great Lakes region is obtained, the pattern of which is confirmed by recent results from Lake Huron²⁷.

Palaeowestward drift

We now consider whether the various characteristic features of the European and North American data labelled in Figs 2 and 3 can be correlated across the North Atlantic, remembering that the Greek labels were initially attached quite independently to both sets of records. In fact a rather striking overall similarity between the patterns, especially for features $\varepsilon - \xi$ will be noted.

Considering the behaviour of the drifting part of the historic field shown in Fig. 1, it would seem reasonable to associate the observed palaeomagnetic inclination maxima and minima with the passage of the broad negative and positive regions of the non-dipole field beneath the respective sites. Thus one wavelength of the pattern of palaeomagnetic variations would be produced by each revolution of the westward drifting sources located in the outer core. Shorter wavelength variations would be caused by the more rapidly evolving structure within each broad negative and positive region and these should produce variations in the shape of the successive maxima and minima recorded at a given site and also some variation in the shape of any given labelled feature as it is recorded first in Europe and then later in North America.

In principle, we should be able to measure the rate of drift in two ways. First, the time taken for 360° of drift of the whole non-dipole field pattern is given by the time between two successive maxima or minima along the palaeomagnetic records. Figure 4 compares rates of drift through the past 12,000 yr estimated in this way, independently for European data and North American data. Dates of the labelled characteristic features have been taken from the Windermere and St Croix/Kylen records which are the best dated for Europe and North America respectively (Tables 1 and 2). Beyond 9,000 yr BP, dates from the Lac de Joux and Black Sea records have been used for Europe. Features ζ and η , originally identified along the UK records for local correlation purposes are not identified in

this discussion with the major source mechanism and have been ignored for the present analysis.

The above method does not give the sense of drift, but this can be checked as follows. Figures 2 and 3 and Table 1 show that each labelled feature is recorded later in North America than in Europe. This phase lag indicates that the sense of drift was westward and corresponds to the time taken for the centre of a positive or negative region of the non-dipole field to drift under the North Atlantic. There is a 90° longitude difference between the Lake Windermere and St Croix sites. Rates of drift estimated by the two methods are consistent with one another (Fig. 4 and Tables 1 and 2).

It is difficult to estimate quantitative errors for the plotted drift rates. These will depend mainly on the accuracy of the calibration of the palaeomagnetic records, on uniformity of deposition rates between levels dated by radiocarbon and also the accuracy with which the centre of each particular feature may be identified. The overall average drift rate before 2,500 yr BP is estimated at 0.15 deg yr $^{-1}$ (s.d. = 0.04), 0.16 deg yr $^{-1}$ (s.d. = 0.02), 0.14 deg yr $^{-1}$ (s.d. = 0.05) respectively for the European, North American and phase difference data points of Fig. 4.

Note that the characteristic times of the features $\alpha - \varepsilon$ are shorter than those of features older than ε . The sharp increase inferred for the drift rate since 2,500 yr BP (Fig. 4) results from the assumption that these shorter 'period' features originated from the same mechanism as the older features. The shorter phase differences observed across the Atlantic for features $\alpha - \delta$ (Table 1) is consistent with this assumption. Nevertheless, the possibility that higher degree terms dominated over the quadrupole term between historic times and $\sim 2,500$ BP needs to be considered. This is because, although the overall westward sense of drift is confirmed by essentially clockwise looping of Bauer plots of declination against inclination with advancing time for UK since $\sim 7,000$ yr BP (ref. 18) and for Lac de Joux since $\sim 11,000$ yr BP, a counter-clockwise loop occurs between

about 1.500 and 700 vr BP for UK data 18 and also for the Greek data²⁰. According to the Runcorn-Skiles rule⁵ this counterclockwise looping indicates eastward drifting geomagnetic sources during the time for which we have inferred fast westward drift. However, this rule breaks down under some circum-

Magnitude of the non-dipole field

In the Northern Hemisphere, the broad negative anomaly has gradually increased in strength from -8,000 to -12,000 nT while the positive anomaly has decreased from +12,000 to +8,000 nT through historic time (Fig. 1a). The magnitudes of these anomalies are too small by a factor of about 3 to account

for the observed amplitudes of the broad palaeomagnetic inclination variations. Thus, we infer that the historically observed non-dipole field intensity has been abnormally low relative to the dipole field intensity. Note that the intensity of the dipole has decreased by 5% per century while the quadrupole moment has increased by ~40% per century since AD 1800.

Conclusions

Overall westward drift has persisted throughout the past 12,000 yr. The average rate of 0.14-0.16 deg yr⁻¹ deduced for 12,000-2,500 yr BP is based on a reasonably secure correlation of inclination variations across the North Atlantic. Correlation of the shorter 'period' features $\alpha - \varepsilon$ is more hazardous and that adopted here must await confirmation from results of a parallel study of declination variations now being carried out. Thus the conclusion that the rate of westward drift increased to about 0.5 deg yr⁻¹ at about 800 yr BP before decreasing to the historical value of 0.25 deg yr⁻¹ should at present be regarded as

It should be possible soon to answer the question of whether the drifting part of the non-dipole field retained its historical, essentially quadrupolar, symmetry through the post-Glacial time by extending the present studies to Southern Hemisphere sites. Clearly this objective can not be achieved by observations restricted to Northern Hemisphere sites.

A full understanding of long period secular variations requires palaeomagnetic data describing the complete geomagnetic vector as a function of time. As yet, methods developed for the determination of past geomagnetic intensities from the intensity of remanent magnetization of sedimentary rocks have not been properly tested by comparison with archaeomagnetic intensity data from the same locality.

The nus mutations affect transcription termination in Escherichia coli

Douglas F. Ward & Max E. Gottesman

Biochemical Genetics Section, National Cancer Institute, Bethesda, Maryland 20205, USA

The nusAl and nusB5 mutations result in a partial suppression of polarity and thus transcription termination in Escherichia coli. As these mutations block the transcription antitermination activity of bacteriophage \(\lambda \) N gene product, they paradoxically seem to enhance transcription termination at phage termination sites. The rho mutation HDF026 displays almost identical properties. These observations suggest that the nusA and nusB gene products may act as termination factors analgous to rho protein.

TERMINATION of transcription serves a dual function in Escherichia coli-to keep each transcription unit, or operon, separate and isolated from its neighbours and to allow fine control of expression within the operon structure. The importance of ensuring the isolation of each operon is demonstrated by the interference with expression when transcription enters an operon from without, either in the sense-direction (refs 1, 2 and S. Adhya and M.E.G., in preparation) or in the opposing direction^{3,4}. The regulation of operon expression by transcription termination within an operon ('attenuation') has been described extensively in the trp (refs 5, 6) and his (ref. 7)

Premature transcription termination can occur as a result of mutations which introduce nonsense codons into structural genes (see ref. 8) thus exposing transcription termination sites which are not normally active. Such mutations are termed

Table 1 Effect of nus mutations on polarity in the gal operon

		Galactokinase activity 32 °C			relative to gal ⁺ parent 42 °C		
Expt	gal	nus +	nusA1	nusB5	nus +	nusA1	nusB5
1	Tam76	0.15	0.20		0.20	0.33	
	TN102	0.06	0.07		0.04	0.05	
	EocB4	0.02	0.02		0.02	0.03	
2	Tam76	0.33		0.50	0.34		0.68
	TN102	0.05		0.09	0.06		0.12

Values represent the ratio of galactokinase (galK) activity in strains carrying the indicated gal mutation, expressed relative to that in the isogeneic gal^+ parent. This normalization eliminates day-to-day variations in the absolute enzyme activites. Activites in gal^+ strains varied from 12 to 29 units at 32 °C, and from 15 to 33 units at 42 °C. Results are the mean of at least two measurements and are accurate to 0.01 (or 10%). As galK is distal to both galT and galE, the level of galactokinase serves as an indication of the polarity of mutations in either of these two genes. Steady-state galactokinase activity was determined in toluenized cell extracts 12 and corrected for cell density. Growth medium was L-broth containing 5 mM D-fucose as inducer of the gal operon. All strains are derived from E. coli K12 strain N4903 (ref. 33). Expt 1 uses a set of isogeneic $nusA^+$ and nusA1 strains. Expt 2 uses isogeneic $nusB^+$ and nusB5 strains.

'polar'. DNA insertions into operons usually cause severe polarity; they can introduce transcription as well as translation termination signals.

Termination at many sites requires the action of the $E.\ coli$ rho protein⁹; rho mutants display reduced or no polarity^{10,11}. Mutations in rpoB have been isolated^{12,13} which restore polarity in some rho mutant strains. Such allele specificity suggests that interaction between the RNA polymerase β subunit and rho occurs during transcription termination.

Development of bacteriophage λ is regulated at the level of transcription termination. Rho-dependent terminators are present beyond λ genes N and cro, acting to limit transcription to these immediate-early genes. When N product is synthesized, however, these terminators are suppressed, and transcription can extend into the delayed-early gene region. As N product suppresses termination at both rho-dependent and rho-independent sites, it may act directly on the transcription termination process, rather than as a simple antagonist of rho¹⁴.

The possibility that pN might interact with RNA polymerase to prevent termination was suggested by the isolation of several mutations in the rpoB cistron which blocked pN activity 15-18 However, Greenblatt (personal communication) has failed to demonstrate binding of RNA polymerase to N protein in vitro; the putative interaction may occur via a nucleic acid or protein intermediary. A phage-specific DNA (or RNA) sequence, nut, located before the first terminator, is necessary for pN activity¹ The involvement of additional proteins in the antitermination reaction is suggested by the isolation of other host mutations which prevent N function. The nusA (ref. 20) and nusB (refs 21, 22) mutations do not correspond to any component of RNA polymerase. The nusA gene product is apparently identical to protein factor 'L', which is required for optimal expression of β galactosidase in a coupled transcription-translation system²³. nusA protein complexes with pN in vitro²³; the product of the nusB gene has not been identified.

Here we investigate the effect of the nusA1 and nusB5 mutations on host and phage physiology. We find that either mutation partially suppresses polarity in E. coli, suggesting that the nusA and nusB gene products may be transcription termination factors.

Effect of nusA1 and nusB5 on polarity in the gal operon

Suppression of transcription termination by the bacteriophage λN gene product is dependent on several host genes. The host

nusA1 (ref. 20) and nusB5 (refs 21, 22) mutations are defective for N action and restore transcription termination at sites on the phage chromosome. It seemed possible that the nus mutations might therefore promote termination in general, in the absence of N product, both on viral and bacterial DNA. To test this hypothesis, we measured the polarity of mutations in the gal operon in wild-type and nus mutant strains. As polarity produced by nonsense mutations, or DNA insertions, results from premature transcription termination, increased polarity would indicate a higher efficiency of termination.

The galTam76 mutation reduces the expression of galK to about 0.15 relative to wild-type levels (Table 1, expt 1). Introduction of the nusA1 allele elevated the relative galactokinase activity to 0.20. This relief of polarity was slightly more marked at 42 °C; galactokinase levels increased from 0.20 to 0.33 in the nusA1 strain. Recall that nusA1 totally blocks N activity and hence exerts its maximal termination effect at 42 °C. This result was contrary to expectation; the nusA1 mutation restores transcription termination in λ and it was therefore expected that nusA1 would increase polarity in E. coli.

Suppression of polarity by *nusA1* was not observed when the strongly polar mutations *galEocB4* and *galTN102*, an IS1 insertion, were assayed (Table 1).

The nusB5 mutation, like nusA1, restricts the growth of λ at high temperature by enhancing termination at sites normally suppressed by the N product. As shown in Table 1 (expt 2), the nusB5 mutation also relieves polarity in the gal operon. As was the case with nusA1, the limited polarity suppression was observed at both 32 and 42 °C.

The nusB5 mutation, unlike nusA1, reduces the steady-state rate of galactokinase synthesis in gal^+ strains (from 41 to 26 units at 32 °C; from 44 to 25 units at 42 °C). In view of the poor growth rate of strains carrying the nusB5 mutation (data not shown), the expression of other bacterial operons, including some required for cell growth, may also be adversely affected by nusB5

Interaction of nus and rho mutations

The experiments presented above suggest that the nusA and nusB gene products promote transcription termination. To determine whether the nus products act independently of rho we investigated whether nusA would influence residual polarity in a rho-deficient strain. galP3 is an IS2 insertion in the galOP region²⁴; it introduces a transcription terminator and is highly polar on the gal operon⁸. Table 2 shows that in the rho112 galP3 background, the nusA1 mutation increased galactokinase activity by more than twofold—from 0.24 to 0.61 at 32 °C, and from 0.30 to 0.85 at 42 °C. Expression of galK was similarly stimulated by nusA1 in a rho15 mutant.

The nusA1 mutation does not always enhance polarity suppression by rho mutations. Suppression of galTN102 polarity by rho112 is not markedly affected by the nusA1 mutation (Table 2).

Table 2 Suppression of polarity by rho and nusA mutations

			nase activity ! °C	relative to gal ⁺ parent 39 °C	
gal	rho	nusA+	nusA1	$nusA^+$	nusA1
P3 P3 P3	+ 112 15	0.02 0.24 0.51	0.02 0.61 0.67	0.01 0.30 0.39	0.02 0.85 0.75
TN102 TN102	+ 112	0.05 0.20	0.07 0.22	0.02 0.23	0.03 0.30
+	112	1.1	1.0	1.2	1.3

Values represent the ratio of galactokinase activity in strains carrying the indicated gal, rho and nus mutations expressed relative to the isogeneic gal⁺ rho⁺ parent. Experimental details are as indicated for Table 1.

Table 3 trp attenuation in nusA1 mutants

Tryptophan synthetase activity						
	+Attenuator	Attenuation ratio				
	(1)	(2)	(1)/(2)			
nusA+ rho+	11	64	.17			
$nusA1$ rho^+	14	56	.25			
$nusA^+$ $rho112$	10	54	.19			
nusA1 rho112	10	51	.20			

Tryptophan synthetase³⁴ activities are expressed as units per mg protein, where 1 unit is the amount of enzyme required to convert 0.1 μ mol indole in 20 min at 37 °C. Growth media was M56 minimal medium³⁵ supplemented with glucose (0.2%), casamino acids (0.05%) and thiamine (1 μ g ml⁻¹), plus 100 μ g ml⁻¹ tryptophan. All strains carry the $trpR^-$ mutation. + Attenuator strains are trpED24 (ref. 36); – attenuator strains are trpED102 (ref. 36). The attenuation ratio is accurate to 10%.

Attenuation in nusA1 mutant strains

The apparent site-specificity of polarity suppression by *nusA1* prompted us to examine transcription termination at the attenuator of the *trp* operon. Several *rho* mutations have been found to increase the expression of *trp* enzymes²⁵, suggesting a possible role of rho in *trp* attenuation.

Two sets of strains carrying combinations of *nusA1* and *rho112* were constructed. The first carried the *trpLD102* deletion which removes the attenuator; the second carried *trpED24*, a deletion similar in size and extent to *trpLD102* but which leaves the attenuator intact. *trp* expression was genetically derepressed by the introduction of a *trpR* mutation.

The effects of *rho* and *nusA1* mutations on attenuation were determined by assaying tryptophan synthetase, the product of the *trpA* and *trpB* genes (Table 3). Unlike other *rho* mutant alleles tested, *rho112* does not significantly reduce *trp* operon attenuation. By itself, the *nusA1* mutation does cause a significant, although small, suppression of *trp* attenuation. This effect was not apparent in the *rho112* background.

Interactions of *nusA* and *rho* mutations affect the growth of E. *coli* and λ

The rho15 and rho112 mutants both fail to grow in rich media at temperatures above 39 °C. In view of the pleiotropic properties of these rho mutations, it has not been possible to ascribe this conditional lethality to failure of transcription termination and, in fact, thermoresistant survivors of rho15 mutants in which polarity has not been restored have been isolated²⁶.

It was surprising to observe that a rho112 nusA1 double mutant grew well at 40 °C (Table 4). In contrast to a singly mutant strain, nusA1 or rho112, the nusA1 rho112 double mutant fails to form colonies at 32 °C. Unlike nusA1, the nusB5 mutation neither suppresses the temperature sensitivity of rho112 mutants nor renders them cryosensitive.

With respect to growth of λ the *rho112* mutation is quite clearly epistatic to *nusA1* or *nusB5*. At 37 °C the growth of λc_{17} is blocked by *nusA1* or *nusB5*; phage growth is restored by the introduction of *rho112* into the *nus* mutant strains (Table 4). In addition, the double mutant supports the growth of λN^- . Thus, the ability of the *nus* mutations to make a phage termination site resistant to N function is dependent on an active *rho* allele.

Discussion

We have presented evidence which implies that the *nus* mutations of $E.\ coli$ have opposite effects in phage λ and bacteria. In λ , the products of the *nus* genes are required for the phage N function to act and therefore λ fails to grow in *nus* mutant strains. As the role of N function is to prevent termination, the *nus* mutations can be considered to enhance transcription termination on λ DNA. However, in $E.\ coli$, the polarity of certain mutations is partially suppressed by the *nus* mutations.

As polarity is caused by premature termination of transcription, the *nus* mutations seem to reduce termination in *E. coli*.

The degree of polarity suppression by nusA1 and nusB5 depends on the polar mutation tested. Partial suppression by nusA1 occurs in the case of weakly polar gal mutations, but little or no relief of polarity is seen with more polar mutations in the gal operon such as galEocB4, IS1 or IS2 insertions. nusB5 is more effective than nusA1 in suppressing polarity and shows some relief of polarity caused by the IS1 insertion mutant, galTN102, particularly at 42 °C. The most marked effect of the nusA1 mutation on polarity is in conjunction with rho112, a rho mutation which has significant residual rho activity. Here, the nusA1 and rho112 mutations act synergistically to suppress a highly polar IS2 insertion.

The nusA1 mutation produces a partial relief of attenuation in the trp operon. An apparent stimulation by nusA protein of the $in\ vitro$ synthesis of RNA polymerase β and β' subunits has been interpreted as suggesting that nusA protein suppresses an attenuator that regulates $\beta\beta'$ expression^{23,27,28}. We have not, however, observed any significant effect of the nusA1 mutation on the synthesis of these RNA polymerase subunits $in\ vivo$ as judged by the incorporation of ¹⁴C-labelled amino acids and visualization of the proteins in SDS-polyacrylamide gels (data not presented).

We have also tested for other interactions between the *nus* mutations and *rho*. With respect to phage growth, *rho* mutations are clearly epistatic to nusA1 or nusB5; λc_{17} , which fails to form plaques on nus^- hosts, grows well on a rho^- nusA1 or a rho^- nusB5 double mutant. For bacterial growth, nusA1 is epistatic to rho^- ; a rho^- mutant which fails to form a colony at $40\,^{\circ}\mathrm{C}$ will do so when a nusA1 mutation is introduced into the strain. The double mutant is, however, cryosensitive and does not survive at $32\,^{\circ}\mathrm{C}$. Introduction of the nusB5 allele into a rho^- mutant does not alter its growth pattern; it remains thermosensitive and cryoresistant.

The thermosensitivity of rho strains is not well understood. The rho15 and rho112 mutant proteins are thermolabile in vitro. Yet the isolation of secondary mutations which suppress the thermosensitivity of the rho mutants, without restoring polarity (at least to those sites tested), suggests that failure of transcription termination may not be the lethal event (ref. 29 and A. Das, personal communication). Furthermore, the wide range defects in the rho mutants-abnormalities in DNA synthesis, in recombination and in oxidative phosphorylationpresents several potential causes for thermosensitivity. The observation that the nusA1 mutation suppresses the thermosensitivity of rho mutants in addition to enhancing suppression of certain polar mutations is not inconsistent with the above analysis. We can imagine that nusA1 affects the pleiotropic character which is responsible for cell death at 40 °C by a mechanism unrelated to transcription termination. Alternatively, the nusA gene protein may act at some bacterial terminators, vital for cell growth, as it does at λ terminators, by stimulating transcription termination.

The *rho* mutant, *rhoHDF026*, has been characterized and seems to be phenotypically very similar to nusA1 and nusB5—polarity suppression is partial and the activity of the λN function is reduced³⁰). The similarity between these mutants is consistent with the idea that nusA and nusB, like *rho*, are transcription termination factors.

Table 4 Interactions of rho, nusA1 and nusB5 mutations

		Cell g	Cell growth		Phage plating	
rho	nus	32 °C	42 °C	λnin₅	λc ₁₇	λN^{-}
+	+	+	+	+	+	
+	A1	+	+	+	****	-
+	B5	+	+	+		
112	+	+		+	+	+
112	A1	-	+	+	+	+
112	B 5	+	*****	+	+	+

In an accompanying article³¹, Greenblatt et al. present evidence that nusA protein acts in vitro as a site-specific transcription termination factor. His results are consistent with our in vivo experiments which indicate that the nusA1 mutation partially relieves polarity in the gal operon. The incomplete relief of polarity by nusA1 is best explained by assuming that nusA1 protein retains considerable termination activity. The paucity of nusA mutants suggests that nusA may have a vital function. λN protein interacts with nusA protein in vitro 23, and presumably in vivo, to antagonize nusA termination function. It is possible that the nusA1 mutation primarily affects the ability of nusA protein to interact with N rather than affecting its transcription termination activity.

The inhibition of λ growth by nusA1 is overcome by introducing a mutation in the rho gene, indicating that transcription

termination caused by nusA1 must be occurring at rho-dependent sites. We cannot eliminate the possibility that other terminators may exist which are dependent solely on nusA protein.

We will be presenting elsewhere evidence that the nusA and nusB gene products interact. It is not unreasonable, therefore, that the nusA1 and nusB5 mutants should have a similar phenotype.

Further investigation of the role of nusA and nusB proteins in bacterial and phage metabolism requires the isolation of additional nus mutations, of secondary mutations which suppress the Nus phenotype and of reproduction of mus protein action in vitro. This work is in progress.

Termination of transcription by nusA gene protein of Escherichia coli

Jack Greenblatt, Marjorie McLimont & Sarah Hanly

Banting and Best Department of Medical Research, University of Toronto, Toronto, Canada M5G 1L6

The nus A gene protein of Escherichia coli and N gene protein of bacteriophage λ interact in vitro and cooperate in vivo to prevent transcription termination. In vitro the nusA gene protein causes RNA polymerase to pause in the t_{R2} terminator region of λ DNA. A completed termination event at t_{R2} requires both the nusA gene protein and the previously described E. coli termination factor rho. The nusA gene protein is therefore both a transcription termination factor and a protein which couples antitermination factors to the elongating transcription complex.

BEYOND the ends of the first genes N and cro of the P_L and P_R early operons of bacteriophage λ are the transcription termination sites t_{L1} and t_{R1} (see Fig. 1). Termination of transcription occurs at these sites in vitro or in vivo only in the presence of the transcription termination factor rho¹⁻⁵. In an infection of rapidly growing Escherichia coli bacteria by phage λ the E. coli RNA polymerase is able to transcribe λ genes distal to the N and cro genes because the product of the N gene of the phage prevents termination of transcription at t_{L1} and t_{R1} (refs 2-11). The N gene protein also prevents termination of transcription at other more distal termination sites in both of the early operons^{4,12–14} It is thought that N protein recognizes particular sites, called nut sites, in the nucleic acid of the λ early operons^{5,15} and somehow modifies RNA polymerase molecules at these sites so that they will resist termination of transcription at most termination sites¹⁶⁻²⁰

Friedman and Georgopoulos and their co-workers (and others) have isolated E. coli mutants in which phage λ cannot grow because its N gene protein cannot prevent transcription

termination²¹⁻²⁴. One such mutation is the nus Al mutation at 68 min on the standard E. coli map, which blocks λ growth at 42 °C, but not at 30 °C (refs 21, 25). The nusA1 mutant protein does not inactivate N protein because the nusA* allele is dominant to the nusA1 allele25. This suggests that the nusA protein is involved in preventing termination of the transcription of λ DNA. That a phage λ N gene mutant, λN punA, grows on nusA1 bacteria at 42 °C (ref. 26) suggests that the nusA gene protein might interact directly with the N gene protein. Recently, the nusA gene protein has been identified as a 69,000dalton acidic protein which binds directly to N protein²²

The nusA gene protein is identical to L factor²⁸, a protein which was purified as an activity necessary for DNA-dependent β -galactosidase synthesis in vitro²⁹. L factor also stimulates the DNA-dependent synthesis in vitro of the β and β' subunits of E. coli RNA polymerase30. These observations can perhaps be rationalized by noting that there is a rho-sensitive transcription termination site in the middle of the lacZ gene³¹ and a probable transcriptional attenuator proximal to the rpoB gene³². These

results suggest that the *nusA* gene protein may have a role in overcoming transcription termination at bacterial terminators.

We have now examined the effects of wild-type and mutant nusA gene proteins on the transcription $in\ vitro$ of λ DNA by E. coli RNA polymerase. Our results show that the nusA gene protein can act to terminate the transcription of the P_R operon of λ . Other experiments, to be published elsewhere 33 , demonstrate that the nusA protein binds specifically, directly and with equimolar stoichiometry to the transcribing form (core enzyme) of RNA polymerase. The nusA gene protein is therefore both a termination factor for RNA synthesis and a protein which can couple transcription antitermination factors, such as the λ N protein, to the transcription complex.

Inhibition of transcription in vitro by the nusA gene protein

In our first preparations of the nusA gene protein we followed the L factor purification scheme of Kung et al.29 and pooled those fractions containing a protein with the same SDS-polyacrylamide gel mobility and isoelectric point as a radiolabelled nusA gene protein standard²⁷. We then noted that preparations of the nusA gene protein at least 90% pure contain an activity that inhibits the transcription in vitro of λ DNA by pure E. coli RNA polymerase (Fig. 2). The dose-response curve is similar to that produced by rho factor¹ in that the inhibition never becomes greater than about 50% even at very high concentrations of nusA protein (Fig. 2). Moreover, as the nusA gene protein does not inhibit transcription in reactions carried out in the presence of rho factor (Fig. 2), our results suggested that the nusA gene protein might be acting to terminate the transcription of λ DNA at a site or sites located either at or distal to the rho-sensitive termimnators.

A consideration of the genetic evidence dealing with the *nusA* gene²¹ and of the biochemical data on L factor^{29,30} suggested that the *nusA* gene protein was involved in preventing the termination of transcription (see above). The idea that it might be causing the termination of transcription was therefore sufficiently unexpected for us to seek convincing evidence that the apparent termination activity present in our purified *nusA* protein was indeed a property of the *nusA* protein itself and not of a contaminant present in the preparation.

Purification of wild-type and mutant nusA gene proteins

Figure 3a,c,e demonstrates that an activity which inhibits λ transcription in vitro has the same chromatographic behaviour as the nusA protein on DEAE-cellulose (Fig. 3a) and hydroxylapatite (Fig. 3c) and the same sedimentation velocity as the nusA protein during centrifugation in a glycerol density gradient (Fig. 3e). In the purification scheme illustrated in Fig. 3 we modified the L factor purification procedure of Kung et al. 29 by using a buffer of higher ionic strength during the high speed centrifugation step and by replacing their gel filtration column

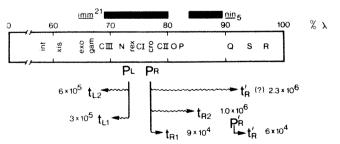

Fig. 1 Partial genetic and transcriptional map of bacteriophage λ . The sizes of the P_R - t_{R1} and P_R' - t_R' transcripts have been determined by sequencing⁴⁵⁻⁴⁷ and the indicated sizes, in daltons, of the other transcripts estimated by electrophoresis^{5,34}. For simplicity, the known λ transcripts beginning at prm, pre, P_O and P_I have been omitted from the diagram. nin_5 is a deletion and imm^{21} is a deletion-substitution.

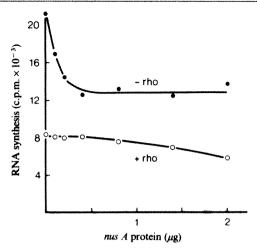

Fig. 2 Effect of the nusA protein on total λ transcription in the absence and in the presence of rho factor. Each reaction contained, in a total volume of 50 μ l, 20 mM Tris-HCl, pH 7.9, 80 mM KCl, 5 mM MgCl₂, 1 mM dithiothreitol, 100 μ M EDTA, 200 μ M each of ATP, CTP and GTP, 50 μ M 3 H-UTP at 16,000 c.p.m. per nmol 2 μ g λ CI₈₅₇S₇ DNA, 1 μ g E. coli RNA polymerase holoenzyme 48 , the indicated amount of nusA protein, and either no rho factor (\bullet) or 50 ng rho factor (\bigcirc). Incubation was for 30 min at 37 $^{\circ}$ C and 3 H-UTP incorporated into RNA was determined using DE81 filters 49 .

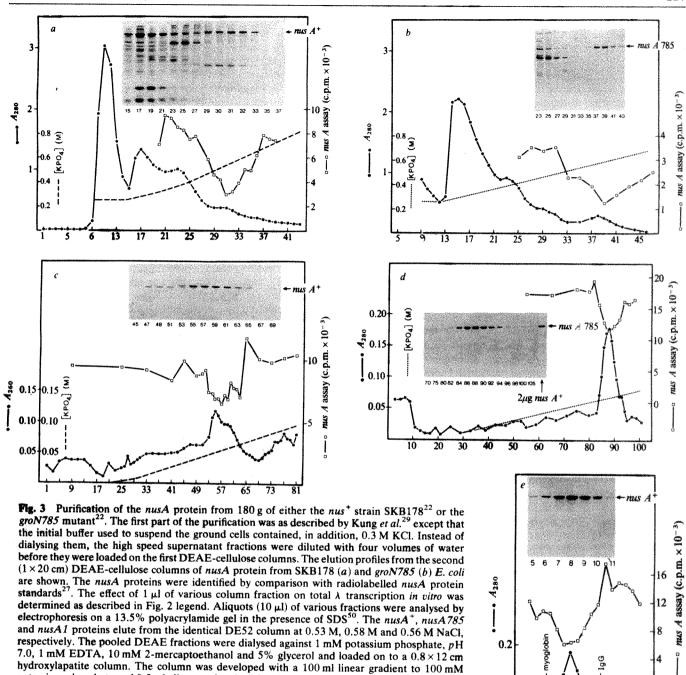

with a hydroxylapatite column. In our hands, at least, the result is a higher yield of nusA protein with a greater degree of purity. The fact that an activity that inhibits transcription of λ DNA in vitro co-purifies with the nusA protein is consistent with the idea that such an activity is indeed a property of the nusA protein.

To establish this point more securely we purified the nusA protein from two strains, nusA1 (ref. 21) and groN785 (ref. 22), that each has a nusA protein with a modified isoelectric point²⁷. We were able to do so because the nusA mutation in groN785 seems to be a silent mutation²⁷ and because the nusA1 mutation is a conditional defect that is very weak at low temperature²¹. Presumably as a result of the charge change or a configurational change introduced by the mutation, each of the mutant nusA proteins behaves somewhat differently from the wild-type protein during chromatography on DEAE-cellulose and hydroxylapatite. The entire purification of the nusA protein from the groN785 strain is illustrated in Fig. 3b,d. Both mutant proteins elute later than the wild-type protein from columns of both DEAE-cellulose and hydroxylapatite.

Our purification scheme leads to a high degree of purity (>90%) for the wild-type nusA protein (Fig. 3e) and for both mutant nusA proteins (see Fig. 3d for nusA785). All three proteins preserve their isoelectric homogeneity throughout the purification (not shown). Most importantly, both the mutant nusA785 protein (Fig. 3b,d) and the mutant nusA1 protein (not shown) co-purify with an activity that inhibits λ transcription in vitro, just as does the wild-type protein (Fig. 3a,c,e). As the behaviours during purification of the three allelic proteins are non-identical, the ability to inhibit transcription of λ DNA in vitro is therefore a genuine property of the nusA gene protein.

Termination of λ transcription in vitro at t_{R2} by the nusA gene protein

We have used gel electrophoresis to examine the effect of the nusA gene protein on λ transcripts made in vitro in the presence of $[\alpha^{-32}P]UTP$. We chose an electrophoresis system used by Roberts³⁴ to analyse λ transcripts made in reactions containing RNA polymerase and no additional factors. Roberts noted that most RNA polymerase molecules transcribing the P_R operon synthesize a large 2.3×10^6 -dalton transcript (see Figs 1, 4a). His mapping data suggested that this long transcript was probably co-terminal, at t_R' , with the short 6×10^4 dalton RNA transcribed in vitro from the late promoter P_R' (Figs 1, 4a).

tively. The wild-type nusA protein was precipitated with ammonium sulphate at 50% saturation and then further purified by centrifugation for 42 h at 40,000 r.p.m. in a Beckman SW 40 rotor through a 10-30% (W/V) glycerol gradient containing 10 mM potassium phosphate, pH 7.0, 100 mM NaCl, 1 mM EDTA and 10 mM 2-mercaptoethanol (e). 1-µl Aliquots of gradient fractions were tested in transcription reactions and 5-µl aliquots were analysed by electrophoresis. The nusA gene protein sediments at 4.2S. The yields of the wild-type and groN785 nusA proteins were, respectively, about 2 mg and 4 mg per 200 g wet weight of E. coli. Each was more than 90% pure, as was the nusA1 protein, purified in a similar manner (not shown).

Some of the RNA polymerase molecules transcribing the P_R operon seem to stop at a site t_{R2} located about midway between t_R' and the rho-dependent terminator t_{R1} (ref. 34 and Fig. 1). The size of the resulting transcript is 1.0×10^6 daltons (Fig. 4a). The t_{R2}-terminated transcript is easily identified as the one which is eliminated by the nin_5 deletion (Fig. 4h), which deletes at least one P_R operon terminator in $vivo^{12,35}$. The P_R operon transcript made from the λnin_5 template is the P_R -t'_R transcript shortened to 1.6×106 daltons by the length of the nin5 deletion. Experiments in which rifampicin was used to synchronize initiation of transcription and then gel electrophoresis to monitor the kinetics of RNA chain elongation (not shown) have indicated that the RNA polymerase molecules pause for an average of

potassium phosphate and 0.5-µl aliquots of various fractions were tested for their effect on RNA

synthesis. The $nusA^+$ protein (c) and the nusA785 protein (d) were located by electrophoresis of 10 μ l aliquots of the various fractions. The $nusA^+$, nusA785 and nusA1 proteins elute from the identical hydroxylapatite column at 50 mM, 66 mM and 62 mM potassium phosphate, respec-

> 1-2 min at t_{R2}; ultimately, all of them synthesize a large 2.3× 106-dalton RNA.

11

15

0.1

The effect of the *nusA* gene protein on λ transcription in vitro is shown in Fig. 4b. It eliminates the long P_R-t'_R transcript and leaves the shorter P_R-t_{R2} transcript. As shown in Fig. 4i, it does not eliminate the P_R - t_R' transcript when λnin_5 , a template which lacks t_{R2}, is transcribed. Thus, the major effect of the nusA gene protein that can be observed by gel electrophoresis is to enhance the efficiency to apparent transcription termination at t_{R2}.

The molar yield of the P_R-t_{R2} transcript made in the presence of the nusA protein is somewhat less than expected based entirely on a termination model (that is, $[P_R-t_{R2}]$ in the presence of $nusA < [P_R-t_{R2}] + [P_R-t_R']$ in the absence of nusA). This is

because RNA polymerase molecules arrive nonsynchronously at t_{R2} , because the nusA protein increases the transit time for RNA polymerase from P_R to t_{R2} by about 50%, and because the nusA protein decreases the rate of RNA chain initiation by about 20% (J. G., unpublished data). These other effects of the nusA protein on λ transcription in vitro can be accounted for by the tight association of the nusA protein with core RNA polymerase at sites other than terminator sites³³ and by competition between the nusA protein and the RNA polymerase σ subunit for binding to core RNA polymerase³³. The experiment of Fig. 2 suggests that the effect of the nusA protein on transcription initiation is, in any case, only minor.

Figure 4e demonstrates that the nusA gene protein is a termination factor that, to be effective, must be present during the transcription reaction. When transcription is carried out in the absence of the nusA gene protein, subsequent incubation in the presence of the nusA gene protein and the transcriptional inhibitor streptolydigin does not result in the conversion of the P_R-t'_R transcript to the shorter P_R-t_{R2} transcript. Therefore, the nusA gene protein is not a ribonuclease that processes the P_R-t'_R transcript to produce a shortened derivative. Kinetic experiments (not shown) have indicated that the nusA protein does not cause irreversible chain termination at t_{R2}, but instead causes RNA polymerase to pause for 10-15 min at several closely linked sites in the t_{R2} region. Irreversible termination at t_{R2} requires both the nusA protein and a low concentration of rho factor (3 µg ml⁻¹, a concentration which does not cause termination at t_{R2} in the absence of the nusA protein).

In the absence of the nusA protein and rho factor, RNA polymerase synthesizes a 6×10^5 dalton transcript from the P_L operon, terminating at t_{L2} (ref. 34 and Figs 1, 4a). Kinetic experiments have indicated that the event at t_{L2} is a pause of very long, but not indefinite, duration (about 10 min) which is not affected by the nusA protein. Hybridization of λ RNA synthesized in vitro to various fragments of λ DNA (J. G., unpublished data) confirmed that the nusA protein inhibits the synthesis of distal RNA from the P_R operon, but has little effect on the synthesis of distal RNA from the P_L operon (unlike rho, which inhibits both). This suggests that, at least in vitro, the nusA protein acts as a strong termination factor for the P_R operon, but not for the P_L operon.

Other large λ RNAs are made in the absence of the *nusA* gene protein and not in its presence (see Fig. 4), and are particularly evident when the nin_5 deletion moves the long t_R' -terminated transcript lower in the gel (Fig. 4h, i). Experiments with λimm^{21} DNA (Fig. 4f, g) suggest that some of them come from the immunity region, but they have not been studied in any greater detail.

Termination of transcription in vitro at t_{R2} by mutant nusA gene proteins

To show that termination at t_{R2} is caused by the *nusA* gene protein and not by a contaminant present in our preparation, we carried out similar experiments with *nusA* protein derived from the *groN785* and *nusA1* strains^{21,22,27}. Thus, *nusA785* protein (Fig. 4l) is just as effective as the *nusA*⁺ protein (Fig. 4k) in terminating transcription at t_{R2} , as is consistent with the lack of phenotype conferred on λ or *E. coli* growth by the *nusA785* mutation²⁷. In fact, the *nusA785* protein is just as effective as the *nusA*⁺ protein at t_{R2} even when the mutant RNA polymerase of the *groN785* strain^{22,36} is used in the experiment (Fig. 4m-o). As the *nusA785* protein behaves differently during purification from the *nusA*⁺ protein (it elutes later from both DEAE cellulose and hydroxylapatite; see Fig. 3), it must be the *nusA* gene protein itself that causes termination at t_{R2} .

The mutant nusA1 protein does behave differently from the wild-type protein (Fig. 5). It is able to cause termination at t_{R2} , but does so with a specific activity several-fold lower than normal. This is true even in reactions carried out at 30 °C and the effect is only slightly accentuated in reactions carried out at higher temperatures. The lack of a strong temperature effect on nusA1 termination activity in vitro is not unexpected: in vivo

experiments have suggested that the nusA1 mutant protein is only temperature sensitive for antitermination²¹, not for termination. The low specific activity of the nusA1 protein is not a consequence of its having been almost totally denatured during purification because the pure nusA1 protein is fully capable of binding to λN gene protein and to RNA polymerase (J. G. and Joyce Li, unpublished data). It seems likely that the reduced activity of the nusA1 mutant protein is adequate or almost adequate in vivo for terminating transcription (see accompanying article³⁷), but inadequate for coupling the N gene antitermination protein to the transcription complex. The fact that the nusA1 protein has an altered t_{R2} termination activity provides additional evidence that it is really the nusA gene protein that causes termination at t_{R2} .

Termination of transcription in vitro at t_{R2} by a mutant RNA polymerase

The experiment shown in Fig. 4p-s suggests that the termination effect of the nusA protein $in\ vitro$ represents a real physiological phenomenon, and is not simply an artefact of our conditions for transcription $in\ vitro$. We purified RNA polymerase from an $E.\ coli$ strain isolated by Lecocq and Dambly³⁸ which has a mutation, rif501, conferring resistance to rifampicin in the β subunit of its RNA polymerase. One of the properties of this strain is its ability to support λ growth at high temperature in the absence of a functional N gene protein³⁸. The experiments of Lecocq and Dambly³⁸ suggest that the rif501 RNA polymerase is resistant in

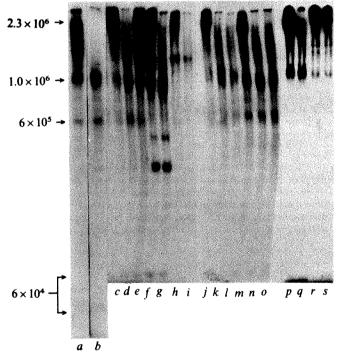

Fig. 4 Electrophoretic analysis of λ transcripts made in vitro. Transcription reactions were carried out as described in Fig. 2 legend except that they contained [α-32P]UTP at 200 μCi per μmol instead of ³H-UTP. Reactions contained the indicated DNAs and, where indicated, 0.5 μg nusA protein. Reactions were stopped with 100 μl of 9 M urea, 1% SDS and aliquots were electrophoresed on a slab gel containing 0.5% agarose, 2.5% polyacrylamide and 0.1% SDS³⁴. a, λ DNA; b, λ DNA, nusA⁺ protein; c, λ DNA; d, λ DNA, nusA⁺ protein; e, λ DNA, reaction stopped with 10 μg ml⁻¹ streptolydigin and incubated for another 30 min in the presence of nusA⁺ protein; f, λ imm²¹ DNA; g, λ imm²¹ DNA, nusA⁺ protein; h, λ nin₅ DNA; i, λ nin₅ DNA, nusA⁺ protein; j, λ DNA; k, λ DNA, nusA⁺ protein; l, λ DNA, nusA⁺ protein; l, λ DNA, nusA⁺ protein; m, n, o, same as j, k, l except RNA polymerase; p, λ DNA, q, λ DNA, nusA⁺ protein; r, s, same as p, q except that the core component⁵¹ of the RNA polymerase was from the nif501 mutant³⁸ instead of from wild-type E. coli.

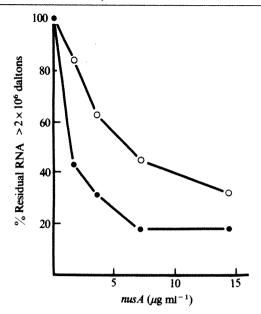

Fig. 5 Comparison of the effects of wild-type nusA protein and the nusA1 mutant protein on λ transcription in vitro. Reactions containing the indicated concentrations of the $nusA^+$ protein (\odot) or the nusA1 protein (\odot) were carried out and the products analysed as in Fig. 4. The high molecular weight regions of the gel tracks were cut out and counted and the results expressed as a percentage of the counts obtained in tracks of reactions containing no added nusA protein.

vivo to termination at terminators of the P_R operon of λ , but terminates normally at the terminators of the P_L operon of λ . As the nusA gene protein is active in vitro on the transcription of the P_R operon, but not on the P_L operon, it seemed likely that the rif501 RNA polymerase was resistant to the nusA protein. As shown in Fig. 4r, s the rif501 RNA polymerase does not respond in vitro at t_{R2} to the presence of the nusA protein. It also has a shorter pause at t_{R2} than wild-type RNA polymerase in the absence of the nusA protein (Fig. 4p, r), but does respond normally at t_{R1} to rho factor (not shown). As the in vitro binding of the nusA protein to the rif501 RNA polymerase seems to be normal, the polymerase may be unable to recognize nusAdependent terminators. These results imply that, at least at high temperatures, the nusA gene protein is an important physiological block to P_R operon expression and λ growth; they also imply that transcription termination in vitro by the nusA gene protein is an in vitro reflection of a phenomenon that occurs in vivo. Additional support for the concept that the nusA protein causes transcription termination in vivo is found in the accompanying article³⁷.

Discussion

We have shown that the nusA protein of E. coli causes RNA polymerase to pause at a site t_{R2} in the P_R operon of phage λ . Final termination and release of the RNA chain at t_{R2} requires a low concentration of rho factor (a rho factor concentration that is ineffective in the absence of the nusA protein) in addition to the nusA protein.

How, then, can we reconcile the action of the nusA gene protein as a termination factor for RNA synthesis with the demonstration by Friedman²¹ that nusA is required to prevent the termination of λ early operon transcription and with the observations of Weissbach and his collaborators that nusA is required for the $in\ vitro$ expression of the genes for β -galactosidase²⁹ and the β and β' subunits of RNA polymerase³⁰? We think that there are two major possible explanations.

The first relies on our observation, to be published elsewhere, that the *nusA* gene protein behaves as an RNA polymerase subunit in causing the termination of transcription. It could, then, alter the entire termination specificity of the enzyme so

that, although it enables the enzyme to recognize a new set of termination sites, it also enables the enzyme to ignore another set of termination sites that it would otherwise recognize. In accordance with this principal, it might cause RNA polymerase to read through the rho-dependent terminator in lacZ (ref. 31) and the attenuator in front of rpoB (ref. 32) even though it causes RNA polymerase to stop at t_{R2} in the P_R operon of λ .

If this idea is correct, it is clearly necessary to repeat, in the presence of the nusA gene protein, all the studies done in vitro on the effects of rho factor on the transcription of various operons. For example, an interesting anomaly is posed by studies on the attenuator of the trp operon of E. coli. Termination at trpA is efficient in vitro in the absence of added factors³⁵ even though genetic studies have suggested that rho factor is involved in termination at trpA in vivo 40. It is also particularly interesting to speculate that the insertion element IS1 may possess nusA-dependent terminators because it has no rhodependent or factor-independent terminators in vitro 41 and yet is polar in both orientations in vivo 42. In fact, it is already known that the nusA protein weakens rho-dependent termination at a terminator in the early region of bacteriophage T7 DNA (M. Chamberlin, personal communication) and that the nusA protein strengthens rho-dependent termination at one site and weakens it at other sites at the end of the trp operon of E. coli (T. Platt, personal communication).

A second intriguing possibility, by no means incompatible with the above, is suggested by our observation that the N gene transcription antitermination protein of bacteriophage λ binds directly to the *nusA* gene protein²⁷. This fact suggests how the nusA gene protein can be necessary for preventing transcription termination at many sites, including t_{R2}, even though it is a termination factor. We imagine that the λ N protein interacts with the RNA polymerase at a nut site by binding to the nusA gene RNA polymerase subunit. A subtle modification of the nusA protein, such as that introduced by the nusA1 mutation, might block proper binding of the N gene protein without significantly interfering with the ability of the modified nusA protein to cause transcription termination. The nusA1 mutant protein, which blocks λ growth in vivo, does indeed have termination factor activity in vitro. We expect that an inactive nusA gene protein would allow λN^- phage to grow and might very well be lethal for the host: these are the properties of a strain carrying the rif501 RNA polymerase, an RNA polymerase which is resistant to the nusA protein in vitro.

We can also imagine that E. coli might possess operon-specific regulatory proteins, analogous to the N gene protein of λ , that bind to the nusA gene protein and alter the termination site recognition properties of the RNA polymerase when it is transcribing particular operons. In the case of the lac operon, such a regulator might enable RNA polymerase to read through the rho-dependent terminator in the lacZ gene and still terminate transcription at the end of the lac operon. Such a regulator, if it exists, would probably have been present in the crude E. coli extract used in the original L factor assay of the nusA protein29. There is no strong genetic evidence for the existence of such a regulator, but some experiments 43,44 suggest that CAP, the 3', 5'-cyclic AMP-binding protein of E. coli, could have such a role. Of course, the existence of such a regulator would not be necessary if the nusA gene protein can by itself prevent transcription termination at the rho site in the lazZ gene.

Microwave emission from flare star AT Mic

O. B. Slee.* I. R. Tuohv.† G. J. Nelson* & C. J. Rennie†

There have been several comprehensive optical and lowfrequency radio surveys of flare stars^{1,2} but much less attention has been directed to the microwave emission from such stars. Slee and Page³ claimed to have detected one short 5-GHz flare from Proxima Centauri, and several weak, short 5-GHz bursts were reported from YZ CMi (ref. 4) and Proxima Centauri (refs 5, 6) during simultaneous X-ray, optical and microwave observations. We describe here the most convincing detection (7σ) vet made of a microwave flare during simultaneous optical and 5-GHz observations of the dMe 4.5 flare star AT Mic on 25 October 1980. This event was notable for its long duration and the good temporal correlation between the optical and microwave intensities. Unless the dimensions of the source are very much larger than those observed for solar flares, the 5-GHz source has too great a brightness temperature to be produced by the gyrosynchrotron mechanism usually invoked for solar microwave bursts. Much higher energy particles or a coherent emission mechanism must be involved in the stellar microwave flare. The observed correlation between the optical and microwave fluxes from this flare support the theories in which non-thermal electrons are responsible for both emissions.

The optical monitoring of AT Mic was conducted using the 26-inch Yale Columbia refractor at the Mount Stromlo Observatory. A series of 1-min exposures on blue sensitive IIaO plates were taken at intervals of ~5 min. No filter was used, but the response of the emulsion coupled with the UV cutoff of the telescope gives a good approximation to a photoelectric B magnitude. Images of AT Mic on the plates were measured with an iris photometer, and the resulting intensity data were normalized relative to a set of comparison stars.

The observing method used in 5-GHz flare observations at Parkes has been described in detail elsewhere3. In the 5-GHz observations high stability against receiver gain fluctuations and thermal emission from passing clouds was achieved by using the equipment in the 'beam wagging' mode. A dual feed at the focus of the 64-m reflector produces two beams which are alternately placed on and off the flare star, a beam switch and synchronous detector being used to extract the difference signal at 39-Hz between the two beams. A complete integration cycle lasts for 1.7 min, with the driving of the telescope, sampling of the data and analysis of the difference signal being controlled by a computer. The r.m.s. fluctuation level for the integrations is

Figure 1 shows the 5-GHz and optical results for the flare on AT Mic on 25 October 1980. Clearly the microwave emission rose rapidly in less than one integration cycle of 1.7-min duration and thereafter declined slowly over the next 60 min. The base level shown dashed in Fig. 1 was obtained by fitting a straight line to the data taken during an identical observation on the previous evening. The slope evident on this base line is caused by the slow rotation of the aerial pattern on the sky, resulting in small changes in the contributions of confusing sources and ground radiation to the on-source and off-source beam configurations. Some secondary intensity changes may be present on the declining side of the microwave burst but their significance is difficult to assess in view of the relatively high noise level.

The optical exposures give a light curve of similar shape with a peak flare increase corresponding to 0.5-1.0 mag; in view of the significantly higher integration cycle time of \sim 5 min (as opposed to 1.7 min for the 5-GHz observation), it is difficult to decide whether or not the microwave and optical flares started simultaneously. The peak optical flux is probably considerably

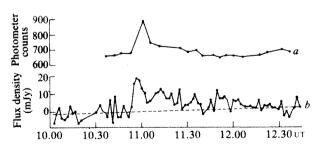

Fig. 1 The optical and 5-GHz light curves for the flare on AT Mic on 25 October 1980. Curve a shows a measure of the density of the photographic images, which were exposed for durations of 60 s at intervals of ~ 5 min. The peak of the optical curve corresponds to a flare luminosity of $\sim 5 \times 10^{30}$ erg s⁻¹. Curve b shows the 5-GHz flux densities, which are averaged over 60 s and taken at intervals of 1.7 min. The dashed baseline was obtained by averaging data taken during an identical observation on the previous evening. The r.m.s. fluctuation in the base line is 2.8 mJy.

brighter than shown in Fig. 1 and occurred near the time of the peak 5-GHz flux density.

The photographic measurements enabled the two stellar components of the AT Mic system to be resolved and thus simultaneously monitored. The two stars, separated by ~4 arc s. are both believed to be flare-active4. Our data unambiguously show that the 25 October flare originated from the southern component of the pair.

There have been previous attempts to observe stellar flares simultaneously at various combinations of X-ray, optical and radio wavelengths^{1-3,5-7}. In fact, only a few flares have been detected simultaneously in more than one of these wavelength ranges. The most striking features of the flare reported here, as compared with the earlier results, are the very long duration and the close correlation between the microwave and optical time

The 5-GHz flare exhibits a temporal variation similar to that observed in very large solar microwave bursts; for these comparatively rare events the well-known, short-lived impulsive phase is followed by a very much extended second phase which typically lasts for ~30 min (ref. 8). Both the impulsive and extended phase of solar microwave bursts are closely associated with hard X-ray emissions^{9,10} and the same population of electrons probably produces both the hard X rays and microwaves^{11,12}. The electrons responsible for the extended phase are generally harder and probably higher in the corona than those generating the impulsive bursts^{8,13}.

It is interesting to consider whether the observed stellar burst can be produced by the synchrotron mechanism which is believed responsible for the solar microwave emissions. In the latter case the synchrotron emission can account for the observed brightness temperatures of up to $\sim 10^9$ K. In the case of AT Mic (assuming a distance of 8.2 pc and a stellar radius of $0.32~R_{\odot}$) the brightness temperature $T_{\rm b}$ of the 20 mJy flare is $8.5 \times 10^9/\beta^2$ K, where β is the diameter of the radio source in stellar diameters. Thus if the emission is synchrotron radiation from ~ 100 -keV electrons $(10^8 < T_b < 10^9 \text{ K})$ the source must have a diameter at least three times larger than the star. If, as is more likely, the source is much smaller than the star, then very much higher brightness temperatures are implied. In this case, particles with energies greater than 100 keV or coherent emission mechanisms need to be considered 1,2,5

Assuming that there are enough high-energy particles in the source region to produce the microwave burst, the same particles (by analogy with the solar flare) may be expected to generate hard X-ray emission with intensity dependent on the ambient (thermal) particle density in the source. Hard X rays have not yet been detected from stellar flares during the several bright optical flares that have occurred during satellite observations in the energy range up to 60 keV (refs 4, 5, 14). On the other hand, soft X rays (0.1-10 keV) have been detected from several flare stars^{6,14,15}, but these are probably of thermal origin and therefore not directly related to the microwave burst.

The observed temporal correlation between the optical and microwave intensities for the flare on AT Mic may only be coincidental. Indeed, if the theory due to Mullan 16 is correct, the optical flare energy is conducted downwards from the coronal plasma which emits the soft X rays. In this case a correlation between the thermal X-ray and optical fluxes would result; any correlation with the non-thermal microwave emission would be much more indirect. On the other hand, if there is a direct relationship between the optical and microwave fluxes, as suggested by the observations in Fig. 1, then theories which are consistent with such a common origin should be investigated. One such theory 17 ascribes the increase in optical brightness to a wavelength shift of IR photons to visible wavelengths by inverse Compton scattering from MeV electrons. The mechanism may be very efficient in the cool flare stars, which have most of their quiescent emission in the IR region of the spectrum. This theory has recently been supported by Bruevich et al. 18, who observed decreases in the IR fluxes of several flare stars immediately before flares in the visible spectrum; the magnitudes and durations of the negative IR flares were sufficient to account for the excess flare energy radiated subsequently in the visible spectrum. The significance of this mechanism for the current observations is that the same MeV electrons responsible for the optical emission could also produce the microwave flare, thus accounting for the observed correlation.

The fact that the present 5-GHz flare on AT Mic lasts much longer than the microwave bursts generally observed either from the Sun or from the flare stars Proxima Centauri^{5,6} and YZ CMi (ref. 4) suggests that the extended part, at least, may result from a previously unobserved mechanism. On the other hand, long-duration optical flares¹⁷ and metre-wave radio bursts² have been previously observed on flare stars. It may simply be that the extended parts of previous stellar microwave bursts have been below the threshold for detection.

We thank Mr I. Wilson for assistance in the 5-GHz observations. The radio and optical observations of AT Mic were prompted by K. Mason and S. Kahn in support of a planned simultaneous X-ray observation by the Einstein Observatory (which unfortunately did not occur).

Fine structure in the ionospheric D-region

E. V. Thrane & B. Grandal

Norwegian Defence Research Establishment, PO Box 25, N-2007 Kjeller, Norway

T. Flå & A. Brekke

Institute for Mathematical and Physical Sciences, University of Tromsø, N-9001 Tromsø, Norway

Assuming that their observations of the weak echoes of high frequency radio waves scattered from the lower ionosphere were caused by Fresnel reflections from discontinuities in the refractive index, Gardner and Pawsey¹ developed a method for determining the height distribution $N_{\rm e}(h)$ of the D-region electron densities from observations of the ratio A_x/A_0 (h) of the back-scattered amplitudes of the extraordinary and ordinary magneto-ionic components. This 'partial reflection' method turned out to be a useful tool for studies of the ionospheric D-region²⁻⁵. We compare here observations of weak radio echoes from the ionospheric D-region, with model computations of radio wave scattering, based on in situ measurements of ionospheric irregularities. The results show excellent agreement, indicating that an important source of the weak partial reflections has been identified.

The nature of the irregularities and the scattering mechanism has been extensively discussed and the theory has been gradually developed to describe different types of scattering 6-13. Part of this discussion dealt with the possibility that the irregularities in refractive index could be due to changes in electron-neutral collision frequency⁷ as well as changes in electron density, as originally assumed by Gardner and Pawsey. Belrose *et al.*¹⁰, however, presented data supporting the original hypothesis, and in the following we assume that only changes in electron density cause the partial reflections. The remaining important problem is to map the structure of these electron density irregularities. Because the air in the D-region is only weakly ionized, the degree of ionization being in general smaller than 0.1 p.p.m., we may expect a close coupling between changes in the ionized and neutral constituents. Studies of irregularities in ionization density may therefore give information about the dynamical state of the mesosphere.

The simple theory of Fresnel reflection implicity assumes that sharp vertical gradients in refractive index exist extending horizontally over at least a Fresnel zone (≈5 km for HF-waves near 70-km altitude). The vertical change in electron density $\Delta N_e/N_e$ must be of the order of 1-8% within a fraction of a radio wavelength (30-100 m) to produce the observed scattered amplitudes¹⁴. A revised theory by Flood⁸ assumes volume scattering from a medium in which irregularities with a spectrum of sizes are present. Constructive interference of backscattered signals will occur where the spatial variations have scales near half the radio wavelength. The radar will therefore preferentially be sensitive to the intensity of fluctuations with such scales. Ground based experiments to determine the nature of the scattering mechanism have not yielded conclusive results, but indicate that both Fresnel reflection from extended irregularities and volume scattering may occur. There seems to be a tendency for the larger irregularities to occur at low heights $(below 70 \text{ km})^{14,15}$.

We now compare observations of partial reflections from the D-region with computed intensities of radio echoes. The model computations are based on volume scattering from irregular ionospheric structures measured in situ in a sounding rocket. The experimental data were obtained from a rocket-borne electrostatic ion-current probe combined with simultaneous recordings of partial reflections. The experiments were made in North Norway, at the Andøya Rocket Range (69°17′N, 16°01′E) and at Ramfjord Research Station (69°58N, 19.22°E) where the University of Tromsø operates a partial reflection facility. The latter station is situated near Tromsø, 120 km to the north-east of the Andøya Rocket Range.

On 1 March 1978 at 01.13UT a research rocket code F-47, was launched from Andøya Rocket Range into a moderately disturbed auroral ionosphere. Before and during launch the ionospheric conditions were monitored by the partial reflection experiment at Ramfjord and by riometers and magnetometers at both sites. The launch criteria were: the presence of strong, stable partial reflections in the height range 65–95 km, and that both riometer absorption and magnetic activity were of similar magnitudes at the two sites. At the time of launch a moderate disturbance with riometer absorption between 0.5 and 1 dB at both sites had lasted for several hours with only small changes in absorption and partial echo structure. Magnetic activity was low during this period.

The F-47 payload was carried by a Nike Apache rocket and reached an apogee of 127.5 km. The electrostatic probe was designed to measure positive ion current with high time resolution and accuracy. The sampling rate was 1,136 Hz, providing one measurement of ion current per metre along the rocket trajectory through the D-region. The rocket experiment and the results have been described elsewhere 16. Some important assumptions made in the analysis of the rocket data should be mentioned. First, the observed ion current I is assumed to be proportional to ambient ionospheric ion number density N_i over small height intervals ($\Delta h \approx 1$ km). As the probe moves through the plasma with a speed about three times larger than the thermal velocity of the ions, the observed time variation in ion current is assumed to reflect the spatial structure of irregularities in the ambient ion density, that is $\delta I/\langle I \rangle = \delta N_i/\langle N_i \rangle$, where δI and δN_i are deviations from the respective running means $\langle I \rangle$

and $\langle N_i \rangle$ taken along a suitable length of the rocket trajectory. Furthermore, local charge neutrality is assumed so that $\delta N_i/N_i = \delta N_e/N_e$ where N_e is the electron number density. The instrument provides power spectra in the scale range 3-100 m. In the D-region the spectral slope is near -5/3, indicating that the irregularities are caused by homogeneous, isotropic turbulence, whereas the spectra observed above 95 km have a 'white noise' character. Of particular interest is the intensity in the D-region of irregularities with scales equal to $1/2 \lambda$ where λ is the radio wavelength of the partial reflection radar. The height variation of this intensity is shown in Fig. 1. The accuracy of the rocket results shown in Fig. 1 depend on several factors. The determination of the relative fluctuations in positive ion density $\sqrt{\langle \delta N_i^2 \rangle / \langle N_i \rangle}$ at the length scale $\lambda/2$ is accurate to better than 5%. The absolute magnitude of the electron density fluctuations is found from the equation

$$\sqrt{\left\langle \delta N_{\rm e}^2 \right\rangle} = \frac{\sqrt{\left\langle \delta N_{\rm i}^2 \right\rangle}}{\left\langle N_{\rm i} \right\rangle} \left\langle N_{\rm e} \right\rangle$$

where the electron density profile $\langle N_e \rangle(h)$ is determined from a radio wave propagation experiment in the rocket (Faraday rotation and differential absorption measurements, M. Friedrich personal communication). The structure in Fig. 1 represents a real variation in the fluctuation intensity, it is not associated with any large-scale structure in the electron density profile $\langle N_e \rangle(h)$, which is a smooth monotonic function of height¹⁶. The absolute accuracy of this profile changes with height from ~30% near 65 km to better than 10% at 95 km. Note that the observed fluctuations in ion density could not have been caused by fast time variations in the flux of the ionizing source (precipitating energetic electrons), because the time constant of the ions in the lower ionosphere is of the order of 100–1,000 s.

lower ionosphere is of the order of 100-1,000 s. The partial reflection experiment (PRE)^{17,18} facility near Tromsø operates on 2.75 MHz ($\lambda = 109$ m) and using a 17 dB gain antenna, transmits circularly polarized, 20 μ s wide, pulses vertically with a pulse repetition rate of 50 Hz. The equivalent

—, Fluctuations derived from the rocket measurements; one of the amplitude of the ordinary magneto-ionic component.

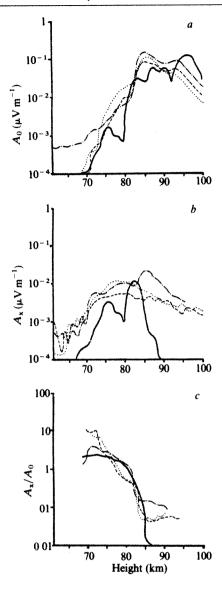

Fig. 2 Comparison between partial reflection measurements and results from calculations of partial reflection amplitudes based on rocket measurements of ionization density fluctuations. Computed values; ----, measurements 01.12.23-01.13.09UT (1 March 1978); ---, measurements 01.13.54-01.14.34UT; measurements 01.15.21UT-01.16.02UT. a, r.m.s. amplitude of ordinary magneto-ionic component versus height; b, r.m.s. amplitude of extraordinary magneto-ionic component versus height; c, r.m.s. amplitude ratio A_x/A_0 versus height.

isotropically radiated peak power is about 125 kW. The polarization is switched between pulses, so that alternate pulses correspond to the ordinary and extraordinary magneto-ionic modes. The transmitter and receiver systems are computer controlled, and the weak partial echoes are recorded on magnetic tape for every 1-km height interval, typically in the height region 50-100 km. Three examples of PRE observations of ordinary echo amplitude $A_0(h)$ and extraordinary amplitude $A_x(h)$, averaged over 40 s intervals during the rocket flight are shown in Fig. 2. The electron density profile $N_e(h)$ may be derived from the ratio $A_x/A_0(h)$, and this ratio is also shown. Observations from the three different time intervals are quite consistent, indicating that no significant ionospheric changes occurred during the flight. The height distribution of electron number density was also determined from Faraday rotation measurements in the rocket (M. Friedrich, personal communication). These number densities agreed well with those determined from the PRE results. Thus the D-region showed no significant changes over a distance of 120 km.

The ratio of received to transmitted powers for the partial reflections may be expressed as 8 (T. F. unpublished data):

$$\frac{P_{R}(h)}{P_{T}} = \operatorname{constant} \frac{1}{h^{2}} \int_{0}^{\infty} dz_{1} g^{2} \left(\frac{z_{1} - h}{2}\right) |C(z_{1})|^{2}$$

$$\times \exp\left(-4 \int_{0}^{z_{1}} k_{i}(z') dz'\right) \tilde{R}(z_{1}) \tag{1}$$

Here h is the height from which the power $P_{\rm R}(h)$ is received, $g((z_1-h)/2)$ represents the pulse shape, $C(z_1)$ is a known function based on an assumed height variation of electronneutral collision frequency 19 , and k_i is the imaginary part of the wavenumber. The constant is determined by calibration of the radar system, and $\tilde{R}(z_1)$ is the intensity of ionospheric fluctuations with scales corresponding to $\lambda/2$ or $2k_r$, where k_r is the real part of the wavenumber.

The relation between the rocket and partial reflection observations was tested in two ways. First, the amplitudes $A_x(h)$, $A_0(h)$ and ratio $A_x/A_0(h)$ were computed directly from equation (1), using values of $\tilde{R}(z_1)$ determined from the rocket probe for 1-km intervals. In Fig. 2 the results of the computations are compared with the measurements. The agreement, both regarding absolute magnitudes and height variation is very good. The main sources of uncertainty are the possible ionospheric changes over the distance of 120 km between the radar and the rocket, and possible inaccuracies in the absolute calibration of the radar system. The discrepancy between calculated and measured amplitudes for the extraordinary wave above 85 km, could be due to contamination of the measurements by oblique echoes, or to the effects of not correcting for the change in the extraordinary mode group velocity above 85 km.

In the second test equation (1) was solved for the term $\hat{R}(z_1)$, using the measured ratio $P_{\rm R}(h)/P_{\rm T}$. To achieve this, the pulse $g((z_1-h)/2)$ was assumed to be a square wave of width 3 km centred at a height h, and all other terms inside the integral were assumed constant within this height range. In Fig. 1 the computed term $R(z_1)$ representing the intensity of the fluctuations is compared with the rocket measurements. Again the agreement is good, although the computations do not reproduce the detailed structure observed in the rocket. At least part of this discrepancy could be due to the fact that the computed fluctuation intensity is averaged over a scattering volume of width

We conclude that the intensity and height variation of partial reflections measured during the rocket flight are consistent with volume scattering from the ionospheric irregularities measured by the electrostatic probe in the rocket. The power spectra of ion density fluctuations derived from the rocket data, indicate that these fluctuations are caused by turbulence in the neutral air¹⁶. We may therefore conclude that such turbulence is an important source of partial reflections.

Photovoltaic conversion by macromolecular thionine films

R. Tamilarasan & P. Natarajan*

Department of Chemistry, University of Madras, Tiruchirapalli 620 020, Tamil Nadu, India

On excitation by light, thionine dye oxidizes Fe^{2+} ions in solution and the photoproducts undergo dark reactions to restore the starting materials. The photogalvanic (photovoltaic) potentials generated by this cyclic process can be demonstrated by means of a cell with two platinum electrodes, one illuminated and one in the dark. Light is converted more effectively into electricity in the totally illuminated thin-layer (TITL) cell with platinum and tin oxide electrodes, but the efficiency of the conversion is limited by energy-wasting back reactions in solution and by restriction on the concentration of the dye¹. We now show that these limitations can be overcome if thick films (~10 μ m) of thionine condensed with macromolecules are coated on to inert electrodes.

Recent investigations of photoredox reactions in heterogeneous media and of charge-transfer reactions in micellar systems², organized monolayers³ and chemically modified electrode systems4 are aimed at understanding the reactions involving biological membranes including photosynthetic apparatus. Microheterogeneous environments drastically change the features of chemical reactions occurring in homogeneous media. In a photoinduced electron-transfer reaction, the products readily recombine in a homogeneous medium to regenerate the starting materials whereas charge separation is favoured in the micellar surface or in organized monolayer assemblies⁵. Such systems could be used to store and utilize light energy. Here we describe the photocatalysed redox reactions induced by the thionine covalently bound to poly(N-methylolacrylamide) and related copolymers. Films of polymer-bound dye were coated on to inert electrodes. The electrode reactions are totally different from those of the excited dye in homogeneous solution.

Purified thionine on condensation⁶ with poly(N-methylolacrylamide) produces the polymer-dye complex, poly(acrylamidomethylthionine-co-methylolacrylamide). Uncondensed dve is removed by dialysing the reaction mixture for several days with water. The ratio of thionine units present to the hydroxymethylacrylamide units in the macromolecular chain could be varied depending on the reaction conditions; the monomer/dye (M/D) ratio in the polymer-dye complex is 120 ± 10 . In solution the dye centres present in the polymeric chain do not form aggregates at this M/D ratio. However, with increasing amounts of dye present in the chain, the dye centres aggregate and blueshift the absorption maximum by 15 nm with respect to the free dye7. Evaporation of the solvent in a flash evaporator at 40 °C leaves behind an insoluble dye-polymer complex: presumably some cross-linking occurs. However, the polymer-dye complex remains in solution without forming a precipitate when the solvent is not evaporated. A drop of the polymer-dye solution placed on a glass or metal surface produces a film on evaporation in vacuum at 90 °C. The absorption spectra of the polymer-dye in solution and of the film coated on to an electrode plate are shown in Fig. 1. In the film some of the dye has aggregated as indicated by the absorption spectrum. In all the present experiments a 1-cm² platinum electrode was coated with the polymer-dye. The film was 12-15 µm thick.

The photoelectrochemical cell consisted of a platinum electrode covered with a film of the polymer-thionine complex, and a plain platinum electrode. The electrodes were immersed in a de-aerated solution containing 10^{-2} M ferrous sulphate in 0.5×10^{-2} M sulphuric acid. The dye-coated electrode was irradiated

A, Poly(N-acrylamidomethylthionine-co-methylolacrylamide); B, poly(N-acrylamidomethylthionine-co-methylolacrylamide-co-acrylic acid); C, poly(N-acrylamidomethylthionine-co-methylolacrylamide-co-yinyl pyridine).

by a 300 W tungsten projection lamp. The open-circuit photopotential ($\Delta E_{\rm oc}$), short circuit current ($I_{\rm sc}$) and maximum power output ($P_{\rm max}$) were measured from the plots of photopotential, photocurrent and power output as a function of applied resistance. The results are shown in Table 1 for the thionine bound to poly(N-methylolacrylamide) and its copolymers. For comparison, the power output and the potential generated on irradiation in identical conditions in the TITL⁸ cell with the distance of 1 mm between the SnO₂ and platinum electrode were measured for unbound thionine. The open-circuit potential measured was -74.5 mV and the power output $0.038~\mu W$ for unstirred solutions. The direction of the current is reversed with respect to the plain platinum electrode in the TITL cell compared with that with polymer-dye film coated electrode.

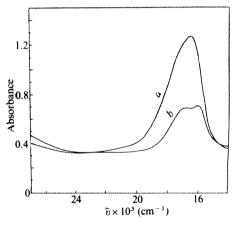

Fig. 1 Absorption spectra of poly(N-acrylamidomethylthionine-co-methylolacrylamide) in aqueous solution (a) and as a film (b).

For the electrode reactions occurring at the dye-coated electrode current-voltage curves were determined in a PAR cyclic voltammeter. The results (Fig. 2) indicate that the thionine-leucothionine couple is more reversible at the dye coated electrode than the Fe²⁺/Fe³⁺ couple. The peak potentials of the polymer-bound thionine/polymer-bound leucothionine are not affected by coating it on to a platinum electrode. However, the cathodic peak potentials of Fe²⁺/Fe³⁺ system is shifted cathodically by 110 mV at the polymer coated electrode compared with the uncoated platinum electrode. Albery et al. have reported that electrolytically coated thionine on a platinum electrode shows a similar behaviour.

That the polymer-dye coated electrode functions as a cathode on irradiation suggests that the electrode reaction reduces Fe³⁺ or some other species. However, the reduction of free Fe³⁺ ions is not a favourable process at this electrode. We propose that the electroactive species is a complex of semithionine with Fe³⁺ ions surrounded by the polymer network along with solvent. As thionine is immobilized in a polymer film the photoproduced semithionine does not undergo the disproportionation reaction

observed in homogeneous medium. The electrode reactions are

Cathode reaction

$$P-TH^{+} + Fe^{2+} + H^{+} \xrightarrow{h\nu} [P-TH_{2}-Fe]^{4+}$$

 $[P-TH_{2}-Fe]^{4+} + e^{-} \longrightarrow P-TH_{2}^{+} + Fe^{2+}$

Anode reaction

$$Fe^{2+} \longrightarrow Fe^{3+} + e^{-}$$

Fe³⁺ ions produced at the anode combine with the semithionine at the cathode to generate the starting materials. The proposed mechanism implies that the oxidation of the semithionine in the complex [P-TH₂-Fe]⁴⁺ present near the electrode seems to be a much slower process than the reduction of the complex at the electrode. Oxidation of P-TH₂⁺ by the Fe³⁺ ions produced at the anode probably occurs by charge migration through interacting thionine-semithionine centres in the polymer network. Charge can be transferred in thin films of dyes and polymers coated on to electrodes and electrons can tunnel through stacks of monolayers 10. However, in quite thick films of polymer a high ohmic resistance is expected to result in negligible amount of current flow. In the present case with the ~15-µm thick polymer film, charge transfer to electrode must be explained either by the migration of charge through the dye centres or the penetration of ferrous ion through the porous polymer network or a combination of both. It has been suggested 11 that the polymer films of 10 µm thickness in suitable solvents exhibit considerable flexibility, which facilitates charge transfer through bound chromophores.

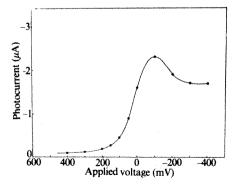

Fig. 3 Photocurrent plotted against applied voltage (versus SCE) across the working electrode-reference electrode for the polymerdye coated electrode.

Decrease in the open-circuit photopotential and the practically negligible amount of current flow observed in the case of poly(acrylamidomethylthionine-co-methylolacrylamide-covinylpyridine) indicates the inhibition of free movement of Fe² ions through the polymer network due to the strong binding between the ferrous ion and pyridine ligand. With the corresponding polyacrylic acid copolymer at pH 2.0, as much of the carboxylic acid is in the protonated form, lack of coordination of acrylate with Fe²⁺ ions does not affect the mobility of these ions through the polymer network.

The polymer-dye coated electrode in the electrochemical cell was illuminated at various applied potentials and the resulting photocurrents are shown in Fig. 3.

The present study has shown that high concentrations of the light absorbers in contact with electrodes facilitate absorption of more light per unit thickness and bring about specific electrode reaction at the electrode. The catalyst, which brings about the light induced electrode reaction, is mounted on the electrode, eliminating unwanted waste-ridden bulk reactions. Comparison of the TITL cells, which show the maximum efficiency for the Fe2+-thionine photogalvanic cell, with the polymer-dye coated electrode system shows that nearly 75% of the power output of the former cell is attained by absorbing light in less than onehundredth of the thickness of the thin layer. As the bulk solution contains no dye, operation of the system becomes simpler. The polymer-dye film is stable for days in the dark and under illumination shows no observable change in its electrochemical behaviour.

This research is supported by grants from University Grants Commission and by the Department of Science and Technology.

Viscosity of high-pressure ice VI and evolution and dynamics of Ganymede

J. P. Poirier, C. Sotin & J. Pevronneau

Institut de Physique du Globe, Université Paris VI, 4, Place Jussieu. 75320 Paris Cedex 05, France

Current models1-5 of the evolution of the jovian satellite, Ganymede, assume that it was formed by homogeneous accretion of water ice and silicate particles (about 50 mass%) with chondritic abundance of the radioactive elements U. Th and K. As the satellite reached its final size it would probably have been composed of a mixture of silicate particles and high-pressure phases of ice, from the centre outwards: ice VIII, ice VI, ice II and finally, near the surface, ice I4. Due to radioactive decay, the temperature would rise in the interior. presumably transforming ice VIII into ice VII, and bringing ice VII and VI close to their melting point. We have measured the viscosity of the high-pressure ice VI at room temperature and pressures of 1.1-1.2 GPa in a sapphire anvil cell; fine particles were used to visualize the flow of ice down the radial pressure gradient. The low value we found for the viscosity $(\eta = 10^{14} \text{ P})$ suggests that solid state convection might have taken place during the early evolution of Ganymede, thus preventing melting and differentiation.

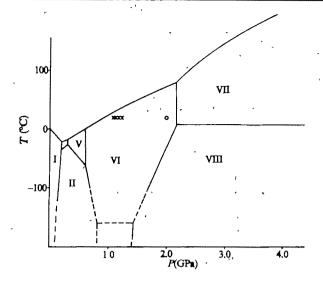

Fig. 1 Phase diagram of ice⁶ showing our experimental conditions (×); and conditions for which the value of viscosity was extrapolated (O).

Parmentier and Head³ have shown that if the viscosity of high-pressure ices near their melting point is lower than 10^{17} P, solid state convection can take place, effectively removing heat and preventing melting and differentiation of the planet. However, if the viscosity is higher than 10^{17} P, melting could eventually occur leading to differentiation and silicates could sink forming a rocky core surrounded by a liquid water mantle and a lithosphere of ice I and II i; if the viscosity of ice I is low enough ($\sim 10^{14}$ P) the lithosphere itself can convect², extract heat from the liquid layer which will freeze in a time of the order of 10^8 yr, and form a mantle composed mostly of ice VI 4 which, in turn, can convect if its viscosity is low enough. More generally, if the viscosity of ice in the interior were as low as 10^{14} P, a steady state body, either differentiated or undifferentiated, would be primarily solid⁵.

Ice VI is easily formed in a diamond anvil cell and observed by optical microscopy⁶. The phase diagram of ice⁷ (Fig. 1) shows that liquid water transforms to ice VI at 0.9 GPa, at 20 °C. For such relatively low pressures, the anvils can be made of sapphire instead of diamond with the result that a gasket with a larger hole can be used, allowing a wider field of observation. The viscosity of the ice can be measured by following the motion of marker particles down the radial pressure gradient in the cell.

A cell of the usual Block-Piermarini type was fitted with anvils machined from a 6-mm diameter single crystalline rod of Al_2O_3 with the c-axis along its length. The anvils were 5 mm

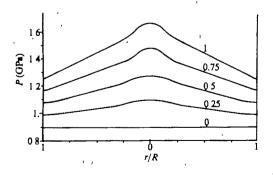

Fig. 2 Hydrostatic pressure in the sapphire anval cell plotted against r/R, where r is the distance from the centre and R the radius of the hole in the gasket. Each curve corresponds to a different load and is labelled in fractions of one turn of the screw.

high and were tapered to an end diameter of 1.3 mm. The gaskets were made of annealed copper foil 0.35 mm thick with a 0.6-mm diameter hole. The hole is filled with tap water containing particles of 2 µm alumina grit and the load is applied, through a lever, by turning a screw (by capillarity, most of the particles stay close to the anvil surfaces); the cell is installed under an optical microscope. At first the gasket is extruded a little inwards, reducing the diameter of the hole and the hydrostatic pressure increases until 0.9 GPa, when ice VI crystals begin to form, and eventually fill the hole. From then on, further increases in the load cause the ice to be extruded outwards and the diameter of the hole to increase slightly. There is a radial pressure gradient from the maximum pressure at the centre to the edge and it can be reasonably assumed that the ice flows fully plastically, having reached its shear strength. In such cases, one can assume that the radial pressure gradient is equilibrated by the shear stresses along the anvil surfaces and that

$$\frac{\delta P(r)}{\delta r} = \frac{2\sigma_{rs}}{h} \tag{1}$$

where P(r) is the hydrostatic pressure at a distance r from the centre, σ_{rz} is the shear stress along the anvil surfaces (in cylindrical coordinates); h is the thickness of the ice disk which can be measured for a given load by focusing the microscope on the

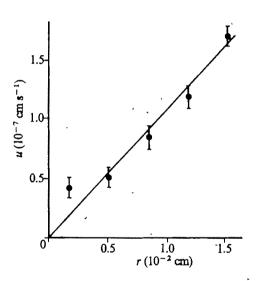

Fig. 3 Plot of the radial velocity (u) of the markers against radius (r).

upper and lower surfaces. P(r) is determined for several values of the load (expressed by N, number of turns of the screw after the ice has formed) by using fixed transition points for alkali halides at room temperature: 0.36 and 1.16 GPa for NH₄F (ref. 9), 0.52 GPa for RbCl (ref. 10) and 1.8 GPa for KBr (ref. 11). Holes in gaskets 150-um thick (the thickness of the gasket when the ice starts to form) are filled with alkali halide powder. As the load is increased the powder first sinters and the transformation appears at the centre of the hole; the transformed phases can be seen as dark circular patches propagating outwards as the load is increased. The pressure at the value of r corresponding to the rim of the dark patch is equal to the transformation pressure. For each of several values of r, it is possible to determine the number of turns of the screw for which the transitions appear; these data are converted into smoothed curves giving P(r) for $\frac{1}{4}, \frac{1}{2}, \frac{3}{4}, 1$ turn of the screw. We assume that the same curves will be approximatively correct for ice VI if we take P(r) to be the pressure over 9 kbar for the same number of turns of the screw after formation of the ice. The pressure distribution in ice VI is shown in Fig. 2.

u is the radial velocity of the particles; $\dot{\gamma}$, the shear strain rate; P, the hydrostatic pressure; $\delta P/\delta r$, the pressure gradient; η , the viscosity; $T_{\rm M}-T$ is the distance to the melting point.

The viscosity has been determined for the load corresponding to $\frac{1}{2}$ turn of the screw after formation of the ice. Microphotographs of the field of ice with particles of alumina close to the anvil surfaces were taken 2 and 17 min after the load was applied. Comparison of enlarged photographs shows that the particles at a distance r from the centre of the cell have moved radially by Δr during the time Δt between the two photographs. Their average velocity $u(r) = \Delta r(r)/\Delta t$ is found to be proportional to $r: u(r)/r = 10^{-5} \,\mathrm{s}^{-1}$ (Fig. 3). The markers are passively carried by the outwards creeping ice. As a first approximation, we take $\dot{\gamma} = u(r)/h$ for the viscous shear rate of ice.

 $\dot{\gamma}$ is related to the shear stress by

$$\sigma_{rz}(r) = 2\eta \dot{\gamma}_{rz}(r) \tag{2}$$

Hence, from equations (1) and (2)

$$\eta(r) = \frac{\delta P(r)}{\delta r} \frac{h}{4\dot{\gamma}_{rz}(r)} \tag{3}$$

For $N = \frac{1}{2}$, $h = 1.3 \times 10^{-2}$ cm. The value of $\eta(r)$ can be computed from the data in Table 1 for values of r corresponding to $\frac{1}{4}R$, $\frac{1}{2}R$, $\frac{3}{4}R$, R (R being the radius of the hole). The viscosity of ice VI at temperatures between 10 and 16 °C below the melting point and pressures between 1.08 and 1.22 GPa varies from 2.4×10^{13} to 1.4×10^{14} P. The accuracy of our determinations is thought to be no better than $\pm 20\%$, $(\Delta P/P \approx 5\%, \Delta h/h \approx 1\%, \Delta u/u \approx 10\%,$ $\Delta r/r = 0$ hence $\Delta \eta/\eta = 20\%$; the viscosity found in a repeated experiment differred by 18%) yet the difference is probably significant and the trend is certainly correct indicating an

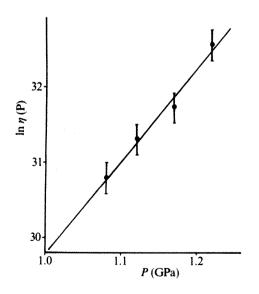

Fig. 4 Plot of the logarithm of the viscosity (η) against pressure (P). The slope of the line gives an activation volume $V^* \simeq$ 30 cm³ mol⁻

increase in viscosity with pressure. The activation volume $V^* =$ $RT(\partial \ln \eta)/\partial P$ can be estimated from plotting $\ln \eta$ against P (Fig. 4), it is found to be approximately $V^* = 30 \text{ cm}^3 \text{ mol}^{-1}$. If we use this value to extrapolate the viscosity at 2 GPa near the ice VI-VII boundary (and 52 °C below the melting point) we find $\eta \simeq 1.7 \times 10^{18} \, \mathrm{P}.$

The assumptions used to determine the viscosity probably lead to overestimating rather than underestimating it; the assumption of fully plastic strain regime (compatible with the fact that the volume variation in the deforming regions has experimentally been found close to zero) leads to an upper limit for the shear stress as does the equilibrium condition (1) for a given load. The annealed copper gasket has been found to be just of the right stiffness to allow formation of ice VI without preventing its creeping outwards (platinum was too soft and Inconel too hard). Finally, we assume in equation (2) that viscous flow takes place under the constant plastic shear stress, which is obviously not correct: some stress relaxation must occur.

Finally, in taking $\dot{\gamma} = u/h$, we made the hidden assumption that the velocity profile across the sample is constant up to the vicinity of the anvils where the particles lie. If we make the more reasonable assumption that the profile u(z) is parabolic with u = 0 at z = h/2 (anvils) and that the particles with the measured velocity u lie at a distance of the anvil surfaces equal to 0.05 h (that is z = 0.45 h), the strain rate is then $\dot{y} = du/dz \approx 20 u/h$, reducing the viscosity by a factor 20.

In these conditions, it is reasonably safe to state that the viscosity of ice VI in most of its domain of existence and within 20 °C of its melting point, is certainly lower than 10¹⁷ P, and may even be lower than 10¹⁴ P. Two important consequences follow:

First, if the accretion of Ganymede was homogeneous, subsolidus convection was possible in the ice VI and most of the planet could have remained undifferentiated.

Second, for reasons not taken into account in the current models (such as rapid accretion rate, tidal dissipation and high initial luminosity of Jupiter), melting and differentiation might occur; in that case the liquid mantle could probably freeze again by lithospheric instability or ice diapirism⁵ and transfer heat by solid state convection.

The distribution of aluminium and silicon atoms on the tetrahedral sites in synthetic faujasites (zeolites X and Y) has been debated for many years. Although the framework structure of the zeolite is known¹, the detailed distribution of Si and Al in the lattice cannot be established by conventional methods, partly because of the very similar scattering powers of silicon and aluminium for X rays and partly because of the difficulties in obtaining crystals of adequate size and perfection. Some inferences have, however, been made on the basis of four indirect approaches: variation of the (cubic) lattice parameter as a function of aluminium content^{2,3}; electrostatic calculations⁴; change of zeolitic acidity on successive extraction of aluminium from the framework⁵⁻⁷; and the kinetics of crystallization⁸. All these approaches have assumed the validity of 'Loewenstein's rule' which forbids Al atoms from occupying neighbouring tetrahedral sites. High-resolution solid-state ²⁹Si NMR (with magic angle spinning) can determine the detailed Si, Al ordering in zeolites⁹⁻¹⁶. NMR coupled with electron diffraction studies has revealed that Loewenstein's rule, generally treated as axiomatic, is broken in Linde $A^{10,13,14}$ and in at least three other zeolites where Si/Al is nominally unity15. In view of its importance as an archetypal zeolite, particularly commercially, we have re-examined the question of framework ordering in faujasite. We propose new ordering schemes and explain discontinuities in the unit cell constant as a function of composition.

The basis of the solid-state NMR method is the fact that ²⁹Si chemical shifts fall into five distinct ranges, depending on whether a given SiO₄⁴⁻ tetrahedron is linked by oxygen bridges to four, three, two, one or no AlO₅⁴⁻ tetrahedra⁷, these ordering modes are denoted Si(4Al), Si(3Al), Si(2Al), Si(1Al) and Si(0Al), respectively (following ref. 7).

We have carried out a detailed NMR examination of synthetic faujasites with Si/Al ratios in the range 1.18-2.42. Spectra were obtained at 20 °C using a Bruker CXP-100 solid-state highresolution spectrometer with a home-made magic-angle-spinning attachment. Cross-polarization and proton decoupling were not used. The conical rotors, ~0.5 ml internal volume, were made from Delrin, an acetal resin and spun at a rate of ~3 kHz. The ²⁹Si spectral line widths at half-height were close to 2 p.p.m. All chemical shifts are given from tetramethylsilane, with high field shifts being negative. Time intervals of 1 s between the radio frequency pulses were allowed, and 2,000-10,000 free induction decays were accumulated per sample. Relative intensities of peaks corresponding to the different Si, Al ordering modes have been measured from the spectra and compared with many speculative distributions of Si and Al generated for each crystal composition. Relative populations of the five types of ordering modes were calculated for each such configuration and compared with experiment. We have given special attention to those configurations which do not involve the creation of a net dipole moment, and those associated with the lowest electrostatic energy. The latter has been approximately calculated for a lattice model with fixed point charges on Al sites.

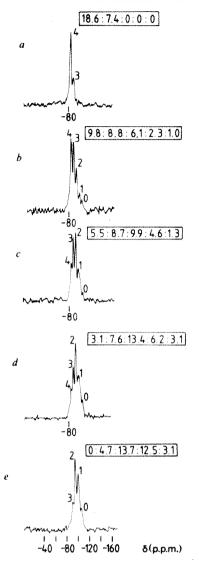

Fig. 1 High-resolution solid-state ²⁹Si NMR spectra of synthetic faujasites. Chemical shifts are given in p.p.m. from tetramethylsilane. Relative populations of the five possible ordering modes, Si(4Al): Si(3Al): Si(2Al): Si(1Al): Si(0Al), estimated from the spectra, are given in the right-hand corner of each box. Peaks corresponding to the respective ordering modes are marked as 4, 3, 2, 1 and 0. The Si/Al ratio for each crystal composition studied, which sometimes slightly deviates from the ideal, is given in the left-hand corner of each box. a, Si/Al = 1.19; b, Si/Al = 1.35; c, Si/Al = 1.67; d, Si/Al = 2.00; e, Si/Al = 2.45.

Unless restrictions are imposed on the size and symmetry of the unit cell, an infinite number of ordered structures is possible. We have considered a basic unit composed of two sodalite cages linked through a hexagonal prism with a centre of symmetry in the middle. Such basic units are, for heuristic purposes, placed at the points of a face-centred cubic faujasite lattice. Each unit contains 24 pairs of tetrahedral sites. The four-fold multiplicity of the F-lattice allows only certain numbers of Al atoms per unit cell of 192 tetrahedral atoms: 96, 88, 80, 72, 64, 56, and so on, equivalent to Si/Al ratios of 1.00, 1.18, 1.40, 1.67, 2.00, 2.42, and so on, respectively. In faujasite there are two distinct types of six-membered rings in each sodalite cage: four 'type I' rings involved in linkages with neighbouring cages, and four 'type II' (non-linking) rings which face the supercage.

The NMR spectra, given in Fig. 1, show that as the Si/Al ratio approaches unity, the ordering converges towards Si(4Al), that is, towards strict alternation of Si and Al in the lattice. This is in contrast to the situation which prevails in Linde A, where the ordering is Si(3Al) (refs 9, 12 and 13), although the zeolite is also built of sodalite cages. The fact that Loewenstein's rule is broken

^{*} To whom correspondence should be addressed.

in Linde A but obeyed in faujasite will be discussed elsewhere. It would seem reasonable to expect that Al-O-Al linkages would be less likely in less aluminous faujasites, that is, those with higher Si/Al ratios. The perfect ordering in a hypothetical faujasite with Si/Al = 1.00 is given as C1 in Fig.2. All sixmembered rings are of the meta type with respect to both Si and Al. Following Dempsey et al.², by now replacing any pair of Al atoms which are related through the centre of symmetry, by Si atoms, thus increasing Si/Al ratio to 1.18, we arrive at configuration C2 with the relative population of the ordering modes of 16:8:0:0:2 which, although the smallest peak cannot be identified, is in good agreement with the intensities in the NMR spectrum (Fig. 1a). Detailed examination revealed that no other speculative configuration can explain NMR results for this composition. The NMR spectra rule out complete disorder.

The transition from Si/Al = 1.18 to Si/Al = 1.40, which is equivalent to altering the Si: Al content per sodalite cage from 13:11 to 14:10, leads to four possible population ratios of ordering modes: 12:8:4:0:4; 10:12:2:0:4; 14:4:6:0:4 (neither shown in Fig. 2) and 8:16:0:0:4 (C3 in Fig. 2), none of which is compatible with the NMR results. However, if we abandon the centre of symmetry requirement and thus the condition of zero dipole moment, we arrive at configurations C4 and C5. C4 agrees very well with experiment (G. Engelhardt, E. Lippmaa and M. Mägi have independently reached the same conclusion) however, C5 (which breaks Loewenstein's rule) does not agree so well with experiment. Approximate calculations of electrostatic energy indicate that either C4 or C5 are acceptable from that point of view. However, the Si (4Al) peak in measured spectra may be higher than Si(3Al) peak, only because the zeolite composition deviates from the ideal Si/Al = 1.40 (see the proportion of these peaks in C2). This means that C5 cannot be unequivocally eliminated.

Closer examination of Fig. 2 reveals that para occupancy of type II rings begins at Si/Al = 1.40 and not at Si/Al = 2.00, as postulated by Dempsey et al.². We suggest that this change in mode of occupancy is responsible for the discontinuity in the plot of lattice parameter, occurring at the composition equivalent to 80 Al atoms per unit cell (that is at Si/Al = 1.40). Note that for any composition para occupancy of a type I ring must lead to the violation of Loewenstein's rule if the centre of symmetry is preserved. There is no violation, however, if para occupancy occurs only in type II rings. For Si/Al = 1.40 it is not possible to limit the para occupancy only to type II sites; some para rings of type I have to be admitted if agreement with NMR data is to be achieved. The resultant loss of centrosymmetry gives rise to a net dipole moment. This may, however, be an acceptable consequence, especially if one considers that small adjustments of cationic positions can compensate that dipole moment and hence retain overall non-polarity.

At Si/Al = 1.67 (a 13:9 ratio, that is two Al atoms are eliminated from C5, one of which was involved in an Al-O-Al linkage) configuration C7 is produced with para occupancy in some type I and II rings. C7 is in good agreement with NMR results. However, an alternative configuration, C6, in which para occupancy is restricted to type II rings, also fits the experimental data. Only very accurate measurements, not feasible at present, could distinguish between the two possibilities

For Si/Al = 2.00 NMR indicates that all type II rings must be of para occupancy (configuration C8). This conclusion agrees with the distribution of Si and Al postulated by Dempsey et al.² and evidently accounts for another discontinuity in the cell parameter plot, observed at Si/Al = 200. Intensities calculated from C8 agree well with experiment. So do those derived from C9 for Si/Al = 2.42, although good agreement with NMR could be achieved in both cases also by abandoning the μ = 0 condition. In other words, for high Si/Al ratios (from 2.00 upwards), ²⁹Si NMR is a progressively less sensitive tool for the choice of Si, Al ordering. It is, however, invaluable in highly aluminous zeolites, where the correct distribution of tetrahedral atoms can be easily identified.

One further discontinuity in the lattice parameter versus composition plot has been observed², at $Si/Al = \sim 2.80$. Although we have no experimental proof, we can speculate, using analogies with more aluminous phases, that the break in the curve is due to the onset of single occupancy of six-membered rings. A configuration in which all six-membered rings are occupied by only one Al atom corresponds to Si/Al = 5.00 and is given in C12. Introduction of partial double occupancy, to reach Si/Al = 3.00 (C10) and Si/Al = 3.80 (C11) involving the necessary existence of meta and para rings, as well as singly-occupied rings, is most likely.

The most reasonable configurations from the many possible are marked with circles in Fig. 2. Unlike any other known and readily applicable technique, ²⁹Si NMR directly probes the immediate environment of the Si atom.

While some of our conclusions may have to be modified when even higher-resolution, higher-sensitivity, solid-state ²⁹Si NMR becomes available, we have already arrived at the progression of

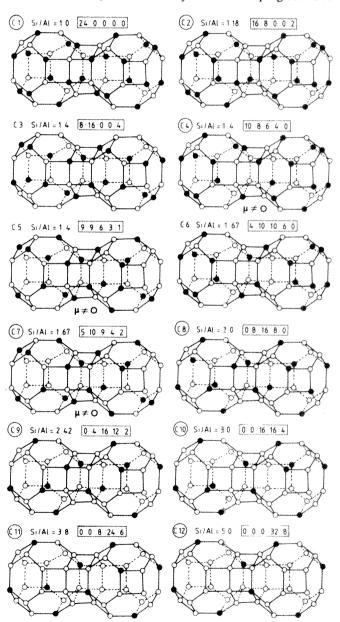

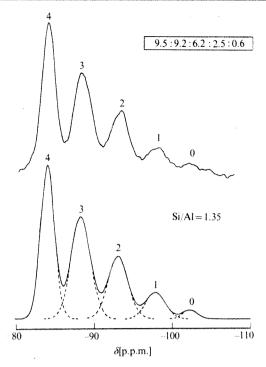

Fig. 2 Possible distributions of Al (●) and Si (○) in the basic structural unit of faujasites with different compositions (given in the left-hand corner of each box). Calculated relative populations of the five possible ordering modes (see Fig. 1) for each diagram are given in the right-hand corner of each box. $\mu \neq 0$ denotes a net dipole moment of the basic structural unit. The most probable configuration for each composition is circled. Configuration C5 violates Loewenstein's rule.

Observed (at 79.6 MHz) a, and simulated b high-resolution ²⁹Si NMR spectra for a Si/Al ratio of 1.35.

ordering schemes that give rise to the following unique configurations of Si/Al ratios of 1.0, 1.18, 2.0, 2.42 and 5.0: (1) at Si/Al = 1.0 and 1.18, all meta configurations for sixmembered rings of both type I and type II; (2) at Si/Al = 2.0and 2.42, para occupancies are limited to only the type II rings; and (3) at Si/Al = 5.0, both type I and type II rings have only single occupancies.

In the intermediate configuration, Si/Al = 1.4, para occupancy occurs in some of the type I and type II rings, with consequential generation of a dipole moment. For Si/AI = 1.67, an extension of the ordering schemes applicable for both 1.4 and 2.0 is possible.

Since this work was completed, we have recorded spectra at much higher resolution, and the conclusions drawn from this recent development vindicate our earlier ones. More precise values of the relative populations are now available, and one of the newly recorded spectra, together with its computer-stimulated analogue (based on Gaussian peak shapes) is shown in Fig. 3.

We acknowledge support from the Universities of Cambridge and Guelph, the SRC, BP Research Centre, and Laporte Industries.

Note added in proof: Since this work was submitted we have heard from Engelhardt and Lippmaa that they have obtained essentially the same results and reached the same conclusions¹

Geophysical evidence for non-newtonian gravity

F. D. Stacey & G. J. Tuck

Physics Department, University of Queensland, Brisbane 4067, Australia

Measurements of the variation of gravity with depth in mines and boreholes permit the densities of intervening rock strata to be inferred. In the few cases in which reliable absolute values of density have been independently determined, the calculations can be used to check the value of the newtonian gravitational constant, G. Such large-scale measurements of G are important because the validity of the inverse square law of gravity at short range is being questioned. We have made such a series of measurements and have found four other data sets in the literature that suffice for the estimation of G. We also report here a statistical analysis of 1,100 km² of overlapping sea floor and sea surface gravity data from the Gulf of Mexico (made available by Exxon). All these estimates of G give values that are higher than the conventional, laboratory-determined one. While the possibilities of systematic errors in these data sets preclude a definite conclusion that Newton's law of gravity fails at short range, the strong circumstantial evidence suggests that well controlled large-scale experiments on the inverse square law are urgently required.

There are theoretical reasons for postulating a non-newtonian gravitational effect^{1,2}, and Long's³ claim that, contrary to earlier, less precise measurements⁴, a departure from the inverse square law is observable on a laboratory scale has stimulated novel experiments on gravity⁵⁻⁷. Essentially evidence is sought that, in terms of Newton's law for the attractive force between masses m_1 , m_2 at separation r

$$F = Gm_1m_2/r^2$$

the factor G is not strictly a constant but varies with r. If it exists, the variation is almost certainly small and at astronomical distances it vanishes altogether, but because we have no way of determining the astronomical scale value of G, it is important to extend laboratory type observations to as large a scale as possible.

The earliest estimates of G were geophysical, relying on the attractive effects of mountains of assumed known masses8. With the acceptance of the superiority of Cavendish-type laboratory experiments the geophysical attempts became of historical interest only, but now that a scale dependence of G is being sought, geophysical measurements acquire a new significance. They permit the measurement of the gravitational constant over distances of 10-5,000 m, greatly extending the normal laboratory range of 0.05-1 m. Of particular interest are measurements of the vertical gravity gradient in mines, boreholes and at depth within the sea. Airy first used this method in a coal mine in Durham and it was later pursued more successfully in Czechoslovakia by Von Sterneck¹⁰. The basic idea is that at depth within the Earth the attracting mass is less than that of the whole Earth by the amount of the shell outside the point of measurement. Domzalski¹¹ emphasized instead the potential usefulness of underground gravity surveying as an exploration tool and in the past 30 yr there have been numerous reports of gravity measurements in mines and boreholes, pursuing this idea, but not referring to the possibility of estimating G. The values obtained from those that enable G to be calculated $^{12-15}$ are compared in Table 1 with our own observations in a mine in North-west Queensland, undertaken specifically to determine G, and a new analysis of marine gravity surveys. These seem to be the only reports that provide sufficient information on independent measurements of rock densities, as well as the

^{*}Result obtained with an assumed deep mass anomaly biasing the gravity profile.

variation of gravity with depth, to permit G to be calculated with formal standard deviations that indicate the scatter of the data. The method of analysis follows closely that used in ref. 7. The values in Table 1 should be compared with the conventional laboratory-determined value of $G = (6.672 \pm 0.004) \times$ $10^{-11} \,\mathrm{m}^3 \,\mathrm{kg}^{-1} \,\mathrm{s}^{-2}$ (ref. 16).

The suspicion that the in situ densities of rock strata are systematically underestimated in core and hand samples makes measurements at sea most important. We have been given access to an extensive set of overlapping sea floor and sea surface gravity data from the Gulf of Mexico (Exxon). The surface and sea floor data were obtained independently at different times. but tied to common sea shore reference stations, and both had been free air and Bouguer-corrected to sea level with the assumption that the sea was filled in with sediment. We have tabulated 703 pairs of sea floor values, with corresponding sea surface values and depth, uniformly spaced over an approximately square area of 1,100 km². We are interested in the difference between the surface and sea floor values g(0) and g(z)as a function of water depth, z. The combined effect of the numerical values used in the adjustments is to subtract 0.068223 mGal ft⁻¹ from [g(z)-g(0)]. Values of $\Delta g =$ [g(z)-g(0)-0.068223 z(ft)] are plotted as a function of z in Fig. 1. If the adjustments were perfect, Δg would average to zero for all values of z, so we are interested in the trend apparent in these rather scattered values. The statistical properties are: n = 703; $\sum_{1}^{n} z = 857782.1$ ft; $\sum_{1}^{n} \Delta g = -802.5$ mGal; $\sum_{1}^{n} z^{2} = 1203853183$ ft²; $\sum_{1}^{n} (\Delta g)^{2} = 2744.7754$ mGal²; $\sum_{1}^{n} (z\Delta g) = -1266254.728$ mGal ft; $\sum_{1}^{n} (\Delta g/z) = -554.61526$ mGal ft⁻¹; $\sum_{1}^{n} (\Delta g/z)^{2} = 2303.2955$ mGal² ft⁻².

We initially having the detection of the linear regression through

these data to obtain the departure of dg/dz from the reference

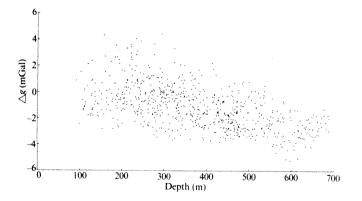

Fig. 1 Gravity differences between overlapping surveys in the Gulf of Mexico. Surface values are subtracted from bottom values after both have been adjusted to correspond to the surface of a sea filled with sediment. If these adjustments were perfect the plotted gravity differences would be zero at all depths, apart from effects of sub-surface features. The scatter of data is due at least partly to sub-surface gravity anomalies.

value (0.068223 mGal ft⁻¹), but a correlation with sea floor topography was noticed. Data from local high points appear systematically above the general trend, although the tendency for data from hollows to give below-average Δg is not as noticeable. The effect may be due to imperfection of the correction for sea floor topography, which was carried out as part of the Bouguer adjustment of the data, but could also arise from a correlation with topography of gravity anomalies from subbottom features; in either case it probably gives an appreciable contribution to the gradient of Δg against z. However, the mean value of $\Delta g/z$ is unaffected by topography; positive and negative contributions to $\Delta g/z$ from underlying inhomogeneities average to zero if a large enough area is properly sampled. Using this average, adding the reference gradient and converting to SI units we obtain the result

$$\frac{dg}{dz} = (2.2124 \pm 0.0020) \times 10^{-6} \quad s^{-2}$$

Using equation (6) in ref. 7, the theoretical gradient is, with numerical values of the geometrical parameters of the Earth

$$\frac{dg}{dz} = 3.089539 \times 10^{-6} - 12.56616G\bar{\rho} \quad s^{-2}$$

and taking the mean value of the seawater density to be $\bar{\rho}$ = $1,027 \text{ kg m}^{-3}$, the observed gradient gives the value of G listed as the last item in Table 1. Alternatively, if we attempt to reduce the error resulting from the greater uncertainties of the $\Delta g/z$ values for shallow data by taking the linear regression constrained through the origin, then the $d(\Delta g)/dz =$ $-(0.526 \pm 0.038) \times 10^{-3}$ mGal ft⁻¹ and the resulting estimate of G is $(6.730 \pm 0.010) \times 10^{-11}$ m³ kg⁻¹ s⁻².

There are possibilities of systematic errors, not represented by the quoted standard deviations, in all of these estimates. In the case of the marine data we rely on the accuracy of reference baseline ties of the two surveys and there is now no effective way of checking these. In the mine and borehole measurements there is a possibility of a systematic discrepancy between in situ and laboratory densities, although this is certainly slight in the case of our own data⁷. We have also considered the possibility of a bias arising from deep anomalous masses. Neither direct measurements⁷ of the free air gradient nor the evidence of a surface gravity survey give evidence of a significant bias. There are sufficient data points in McCulloh's tabulations to provide an internal check and these data are of particular interest because of the small standard deviation that they give. Of the 35 gravity values, we ignored the top 4 which were in the weathered surface layer where densities are unreliable. In Table 1 we have also treated three subsets of 11, 10, 10 of the remaining values. We have also considered the bias of a deep mass anomaly by least square fitting the data with the postulate of an anomalous mass of arbitrary size and depth, without materially affecting the estimate of G.

The evidence of a high value of G is not conclusive but is strongly circumstantial-better controlled experimental data are needed and two new experiments are planned. One is to

measure gravity profiles to a depth of about 4 km in topographically and gravitationally flat areas of the ocean 17 other involves a balance comparison of the weights of 10-kg masses suspended in evacuated tubes at different depths in a lake which will undergo rapid level changes during operation of a hydroelectric pumped storage facility and will offer the possibility of the most precise measurement of G so far.

We thank the Exxon Company for the opportunity to examine gravity records and Michael Alexander and Leroy Brow for helping to make effective use of them.

Structure of the Earth's inner core

David R. Fearn* & David E. Loper

Paul H. Roberts

School of Mathematics, The University, Newcastle upon Tyne NE1 7RU, UK

Jacobs proposed that the Earth's inner core is growing through the freezing of outer-core material as the Earth gradually cools². Recent studies have shown that compositional effects associated with this freezing process can release energy at a rate sufficient to power the geodynamo^{3,4} and may be crucial in determining the dynamic state of the outer core⁵. Here we investigate the effects of composition on the freezing process itself, drawing on metallurgical experience, and speculate on the structure and state of the inner core. We propose that the interface separating the inner and outer core is dendritic and argue that the region in which freezing takes place may extend throughout the entire inner core. Consequently the compositionally driven convective motions which stir the outer core and sustain the geodynamo also occur within the interdendritic spaces of the inner core. The seismic evidence which corroborates this proposal is briefly reviewed.

The material composing the Earth's core has often been treated as being pure iron but it is in fact an "uncertain mixture of all the elements"6. The freezing of a mixture can be very different in nature from the freezing of a pure substance so it is most important that the effects of composition be included in any study of the evolution of the Earth's core. In particular there are two properties which must be modelled. First the temperature (the liquidus temperature $T_{\rm L}$) below which material freezes out of a fluid with a certain composition is a function of that composition. Second, in general, the composition of the solid which freezes is different from that of the fluid from which it has frozen. As a first step towards investigating the effects of composition we shall study the simplest possible system which incorporates these two properties; a binary alloy. We shall assume that as freezing proceeds, one component of the binary mixture goes to form the solid while the other is expelled into the remaining fluid. We shall use ξ to denote the mass fraction of the latter (so by definition $\xi = 0$ in the solid). As already mentioned, the liquidus temperature is a function of composition and we shall use ξ_e to denote that composition ξ for which T_1 takes its minimum T_e . In applying the results of studies of binary alloys to the Earth's core, it is very likely that ξ represents the less dense constituents and the solid which freezes is richer in the denser constituents.

A binary mixture in a single liquid phase has, by Gibbs' phase rule, three independent thermodynamic variables. When a solid phase is present in equilibrium with the adjacent liquid, a constraint is placed on the variables reducing the number of independent variables to two. Usually the constraint is expressed as the liquidus condition $T = T_L(p, \xi)$ where T is the temperature of the liquid and p is the pressure. If

$$T < T_1(p, \xi) \tag{1}$$

the liquid is said to be supercooled and is unstable to the growth of solid, usually in the form of dendrites extending from a boundary. In particular if this condition is caused by a spatial gradient of composition normal to a freezing interface, the liquid is said to be constitutionally supercooled. To determine whether equation (1) is satisfied near the inner-core boundary of the Earth, let us assume the boundary to be spherical and T = $T_1(p, \xi)$ on the boundary. Expanding equation (1) as a Taylor series in powers of $p-p_0$, where p_0 is the pressure at the boundary, and keeping only the linear terms allows equation (1) to be rewritten as

$$(T/L)(\delta - \bar{\mu}\xi \, d\xi/dp) < dT/dp \tag{2}$$

evaluated at the boundary, where L is the latent heat, δ is the specific-volume change on melting, $\bar{\mu}$ is the energy of mixing⁹, and

$$\partial T_{\rm L}/\partial p \equiv T\delta/L, \qquad \partial T_{\rm L}/\partial \xi \equiv -T\bar{\mu}\xi/L$$

Because fluid motions are inhibited at the rigid freezing boundary, the fluxes $\xi \dot{m}$ of light material and $L\dot{m}$ of heat, generated by the freezing of material at a mass rate m per unit area, must be removed from the interface by diffusion. In addition to the usual flux down the gradient, there is an upward barodiffusive flux of light material, giving 9.10

$$\xi \dot{m} = \rho^2 Dg[(\bar{\delta}/\bar{\mu}) + d\xi/dp]$$
 (3)

$$L\dot{m} = k\rho g \, dT/dp \tag{4}$$

where ρ is the fluid density, D the material diffusion coefficient, g the acceleration due to gravity, δ the specific-volume change with composition and k the thermal conductivity. In writing equations (3) and (4) we have assumed a hydrostatic balance to replace radial derivatives by derivatives with respect to pressure. Using equations (3) and (4) to eliminate $d\xi/dp$ and dT/dp from equation (2) yields

$$\dot{m} > \dot{m}_c = (\delta + \xi \bar{\delta}) \rho^2 g D / \bar{\mu} \xi^2$$
 (5)

In writing equation (5) a thermal term, which can be shown to be negligible, has been neglected. This is the condition for constitutional supercooling to occur in the liquid outer core immediately above a spherical inner-core boundary.

Using parameter estimates from ref. 11 ($\rho = 1.2 \times 10^4 \text{ kg m}^{-3}$, $D = 3 \times 10^{-9} \,\mathrm{m}^2 \,\mathrm{s}^{-1}$ $\bar{\mu} = 4.4 \times 10^7 \, \bar{\mathrm{J}} \, \mathrm{kg}^{-1}$ $g = 4.3 \text{ m s}^{-2}$ $\rho \bar{\delta} = 1.1$, $\rho \delta = 0.016$, $\xi = 0.05$), the critical growth rate is $\dot{m}_c = 10^{-10} \,\mathrm{kg} \,\mathrm{m}^{-2} \,\mathrm{s}^{-1}$. On the other hand, assuming the solid inner core formed 3,000 Myr ago and grew at a constant rate since then, we have $\dot{m} = 5 \times 10^{-8} \text{ kg m}^{-2} \text{ s}^{-1}$. By these estimates, the inner core is growing at a rate roughly 500 times faster than the critical value for the occurrence of constitutional supercooling. Even allowing for a considerable variation in the parameter estimates, it appears that if the inner-core boundary were

^{*} Present address: Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Silver Street, Cambridge CB3 9EW, UK

spherical, the fluid immediately above it would be constitutionally supercooled. With the above parameter estimates, the supercooling increases with distance from the boundary at a rate of 0.8 K m⁻¹. It is extremely doubtful that such a strongly supercooled fluid could persist for long in the vicinity of a solid crystalline interface. Studies by metallurgists⁷ of the freezing of binary alloys have shown that for growth rates satisfying equation (5), the system reduces the local rate of freezing \dot{m} by increasing the surface area over which freezing occurs, most commonly by forming dendrites extending into the fluid.

The process of freezing and dendritic growth has been described by Copley, et al. 12 who studied the evolution of a solution of ammonium chloride in water as it was cooled from below. This solution was studied because it is transparent, allowing the freezing process to be observed directly, and because it has a low entropy of fusion, thus solidifying, as would a metallic solution¹³⁻¹⁵. The cooling causes crystals of ammonium chloride to freeze onto a dendritic interface at the bottom of the solution. The interdendritic liquid is enriched in water and hence is lighter than the overlying solution. This unstable layering drives convective motions despite the stabilizing temperature gradient. The buoyant plumes of lighter fluid erode the dendrites and create isolated chimneys free of solid.

In a quasi-steady state, the cooling system studied by Copley et al.12 may be divided into three regions: a lower region completely solid, an upper region completely liquid and a middle region, the 'mushy zone', in which both solid (dendrites) and liquid are present. The compositionally driven convective motions circulate throughout the upper two regions. The top of the mushy zone is the level at which $T = T_L(p, \xi_0)$ where ξ_0 is the mass fraction of the less dense constituent (water) in the wellmixed upper region, while the bottom is the level at which $T = T_{\rm L}(p, \xi_{\rm e}).$

The mushy zone may be thought of as a layer which matches the composition ξ_0 of the upper region to the lowest-meltingpoint composition ξ_e . The thickness of the zone thus depends on the difference $\xi_e - \xi_o$. In the laboratory the dependence of the liquidus temperature on pressure is unimportant and the imposed temperature gradient is sufficiently large that the mushy zone is only a few centimetres deep. In the Earth, pressure effects are important and the temperature gradient is much smaller, causing the mushy zone to be much thicker. To estimate its thickness, the liquidus relation may be rewritten as

$$g\rho\delta dr = -\bar{\mu}\xi d\xi - (L/T) dT$$
 (6)

Within the mushy zone, dT/dr < 0 and a lower bound on its thickness can be found by setting dT = 0 in equation (6). Integration yields

$$g_{o}\rho\delta(r_{o}^{2}-r^{2})/r_{o} > \bar{\mu}(\xi^{2}-\xi_{o}^{2})$$
 (7)

where $g = g_o r/r_o$, subscript o denotes conditions at the innercore boundary (at the top of the mushy zone) and we have assumed $\bar{\mu}$, ρ , δ , r_o and g_o are constant. We may use this inequality to calculate the greatest compositional difference which can be accommodated by a mushy inner core. Setting r = 0, $\xi = \xi_c$, $r_o = 1.2 \times 10^6$ m and using the parameter estimates given previously, equation (7) predicts that $\xi_e - \xi_o < 0.016$. This figure is, of course, very uncertain. If we had chosen a larger value of ξ_0 , say 0.15, then the allowable difference would have been smaller: $\xi_e - \xi_o < 0.006$. An independent bound on the compositional difference sustained by a mushy inner core can be found using Fig. 5 of ref. 16. With the pressure difference across the outer core known¹⁷ to be 1.93×10^{11} N m⁻², the liquidus gradient may be estimated as $(d\xi/dp)_T \le 10^{-13}$ m² N⁻¹. With the pressure difference across the inner core being17 $10^{10} \,\mathrm{N} \,\mathrm{m}^{-2}$, it follows that $\xi_e - \xi_o \le 0.003$.

Whether the composition of the core satisfies such an inequality is not known. The point of this calculation is to show that the thickness of the mushy zone is strongly dependent on the difference in composition between the outer core and the corresponding liquid with the lowest melting point. In fact, unless the two compositions are very nearly equal, the mushy

zone will be very thick, possibly extending to the centre of the

When the idea of compositionally driven convection in the core was first introduced, it was assumed that the resulting flow patterns would be quite similar to those found in thermally driven convection. With the model of a dendritic inner-core boundary, that assumption is not valid. As the core gradually cools, compositionally buoyant fluid is produced within the inner core. This fluid rises upwards into the outer core as thin plumes and is replaced by a general downward motion of heavier fluid. An important feature of this flow pattern, resulting from the fact that diffusion of material is very slow, is that all streamlines must pass through the inner core. Models of fluid flow within the outer core, such as those constructed for kinematic dynamo problems, should have this property.

There may be some seismic evidence which corroborates the view that the inner core is in a partially molten state. Specifically, several authors 18-20 have suggested that the attentuation of seismic waves in the inner core may be due to the presence of fluid inclusions. It has also been demonstrated experimentally²¹ that the anelasticity of a simple binary system (NaCl-H₂O) is much larger if partially molten than if completely solid. Several attempts 19,20 have been made to demonstrate that thermal diffusive effects in a partially molten inner core can account for the observed anelasticity, but preliminary calculations show that compositional effects are likely to dominate thermal effects; whether these can account for the observed anelasticity remains an open question.

Iron-manganese banding in Oneida Lake ferromanganese nodules

Willard S. Moore

Department of Geology, University of South Carolina, Columbia, South Carolina 29208, USA

Ferromanganese nodules in the deep-sea and in freshwater lakes usually accrete layers rich in manganese oxides alternating with layers rich in iron oxides1. The mechanism producing these alternating layers is unknown; indeed, the mechanism producing the nodules themselves is unknown. In Oneida Lake, a large freshwater lake near Syracuse, New York, precipitants from the lake water and the surfaces of nodules at the sediment-water interface are enriched in Mn, whereas nodules buried in lake sediments have surface layers enriched in Fe. It is hypothesized here, using field and laboratory evidence, that reduction and mobilization of Mn from the nodule surface during periods of anoxic sediment cover produce the high Fe layers observed in the nodules.

Oneida Lake nodules have been the subject of several investigations²⁻⁶. Mn phases present are 10 Å manganite (todorokite) and δMnO_2 ; Fe phases are goethite and X-ray amorphous ferric oxides and hydroxides^{4.5}. The nodules exhibit a discontinuous growth pattern characterized by periods of rapid growth interrupted by periods of no growth or erosion⁶. The nodules are most abundant in the 5-10 m deep central area of the lake where $\sim 25\%$ of the bottom may be covered with 1-20 cm diameter diskoidal nodules⁵.

The Mn/Fe ratio of freshly precipitated (<5-yr old) ferromanganese deposits in Oneida Lake is in the range 2.7-3.8 (Table 1). These thin deposits (<1-3 mm) show no Fe-rich layers. The surface Mn/Fe ratios of most Oneida nodules exposed to the Lake water are in this same range (ref. 6 and Table 2). These data suggest that freshly precipated Oneida ferromanganese deposits including nodule surfaces have a Mn/Fe ratio >2; yet in bulk composition the nodules have Mn/Fe ratios of 1.8 with some layers having ratios as low as 0.07 (ref. 5 and Table 2).

Extensive wind-induced mixing prevents the bottom waters of Oneida Lake from becoming anoxic as many eutrophic lakes do in the summer⁷. Although there is no long-term record of sediment deposition on the central shoals where nodules lie unconformably on a weathering Silurain shale, seasonal events may produce fine-grained sediment cover on these nodules depleating O2 and leading to the reduction of surficial MnO2. In anoxic sediments (those containing $\leq 3 \,\mu\text{mol O}_2 \,\text{kg}^{-1}$) MnO₂ reduction is largely completed before Fe₂O₃ reduction begins⁸. These studies have been confirmed in Oneida Lake sediments¹⁰. Thus nodules buried in sediments should have Mn mobilized from their surfaces in preference to Fe. The Mn may diffuse into the nodule or the adjacent sediment pore water. At site 123 in the lake (see Table 2), such a fine cover was observed during June 1977 but not in August 1977; the sediment cover was absent in August 1978 but present in June 1979. This sediment consisted primarily of organic-rich diatom shells, probably resulting from periods of high productivity in the near-surface waters of the lake⁷. Nodules covered by these anoxic sediments should lose Mn and become enriched in Fe on their surfaces. Removal of the sediment cover by oxidation and winowing would leave a nodule surface enriched in Fe available to receive more MnO₂.

The degree of surficial reduction depends directly on the length of time the nodule is covered and the O_2 demand of the sediment. In extreme cases most of the Mn may be removed from a considerable thickness of nodule producing a major Fe-rich band. In other cases Mn accretion may continue relatively uninterrupted for many years to produce a thick Mn-rich band.

There are two sets of data which suggest that these conditions produce the banded structure of the nodules. The first are measurements of low Mn/Fe ratios ranging from 0.07 to 0.31 (Table 2) on the surfaces of nodules recovered from beneath 15-25 cm of sediment in the lake. Below this surface layer, a Mn-rich layer is often present with Mn/Fe ratios of 2-4 (Table 2). Fe-rich layers seem to be forming on these buried nodules. Second, surface depletions of Mn were produced in laboratory experiments by burying nodules in lake sediments for 6 months. In all cases a 1-mm thick layer rich in Fe and depleted in Mn was produced on the nodule surface (Table 2). When the burial

experiments were conducted in covered glass jars, a ring of MnO_2 appeared on the glass at the sediment-water interface. In jars of similar sediment but without nodules, no ring of MnO_2 appeared.

The results of these nodule burial experiments are unequivocal. A skin rich in Fe and depleted in Mn is produced by burying a nodule in lake sediments for several months. Apparently MnO₂ on the nodule surface accepts electrons from carbon oxidation in the sediments and is mobilized as Mn²⁺. In the jar experiments some of this Mn²⁺ diffused to the sediment surface where it was reoxidized to MnO₂. Because the jars with the sediment but no nodules showed no MnO₂ ring, this Mn must have come from the nodules. No similar Fe mobilization was evident.

Besides explaining the Mn-Fe banding of the nodules, the hypothesis answers an additional question concerning the Oneida nodules, namely their episodic growth. It has been shown⁶ that periods of rapid growth (>1 mm per 100 yr) are separated by growth hiatuses which may last 500-1,000 yr. These growth hiatuses may in fact reflect periods of extensive chemical erosion of the nodules during which Mn is removed selectively and a lag deposit rich in Fe forms on the nodule surface. These hard, Fe-rich layers provide structural integrity for the nodules. The Mn-rich sections are cut easily with a steel blade, but some Fe-rich layers have a hardness > 6 enabling the nodules to resist erosion. The partial dissolution of the nodules thus seems to be instrumental in producing a framework strong enough to become an important component of the lake sediments.

I thank Ken Nealson for field assistance and helpful comments, H. Chen for performing the analyses and Dee Hansen for

typing the manuscript. This work was supported in part by NSF grant OCE 7826846.

N₂O exchange between a grassland soil and the atmosphere

J. C. Ryden

The Grassland Research Institute, Hurley, Maidenhead, Berkshire SL6 5LR, UK

The recognition that NO, derived from atmospheric N2O, is an important factor in the destruction of stratospheric ozone1, and that atmospheric N2O may reduce radiative heat loss from the Earth's surface², has stimulated interest³⁻⁶ in the global sources and sinks for N2O. One possibility is that increasing use of industrially fixed N in agricultural production increases loss of N2O to the atmosphere. Until recently, however, field data for the evaluation of this concept were not available. Even now, only a few longer-term studies of N2O loss from representative agricultural land permit estimates of loss over a complete year or a cropping season. In the present study, field measurements of N2O exchange over 12 months between a grassland soil and the atmosphere indicated that the soil acts as both a source and a sink for atmospheric N2O, depending on soil conditions and the amount of nitrogenous fertilizer applied.

The measurements of N₂O exchange (as described in Fig. 1) were made in duplicate in a 10×10 m subplot within a 0.4-ha plot sown to perennial ryegrass (Lolium perenne L.) and receiving 250 kg N ha⁻¹ yr⁻¹ as ammonium nitrate. The field plots formed part of a long-term study of nitrogen fertilizer application to grassland by ICI Ltd at Bracknell, Berkshire, UK. Quadruplicate measurements of N2O exchange were also made on an unfertilized control strip alongside the 250 kg N ha treatment. The soil at the site is a loam in the Wickham series overlying London clay7 (Ochraqualf; US Comprehensive Soil Classification). Some properties of the upper 20 cm of the profile are: pH = 6.0-6.5; organic $C = 34.7 \text{ mg g}^{-1}$; total N = 2.3 mg g^{-1} ; bulk density = 1.06 g cm^{-3} .

Nitrous oxide exchange varied appreciably with time of year and prevailing soil conditions. For the 250 kg N ha⁻¹ treatment (Fig. 1) there was a net loss of N_2O from the soil, weekly mean rates of N_2O loss being as high as 245 ng N m⁻² s⁻¹ (1 ng N m⁻² s⁻¹ = 8.64×10^{-4} kg N ha⁻¹ day⁻¹) after the third fertilizer application which was made during a period of frequent rain. The highest rates of N₂O loss were observed when the following conditions prevailed simultaneously in the upper 20 cm of the soil profile; water content >20% by weight (air-filled porosity <38% of an undisturbed soil volume), nitrate and ammonium contents >10 µg N per g soil and temperature >10 °C. Additional measurements indicated that the highest rates of N₂O loss were also associated with water content >35% in the upper 2.5 cm of the soil profile.

Low rates of N₂O loss (<12.0 ng N m⁻² s⁻¹) were observed following the first and fourth fertilizer applications. These periods of low N2O loss coincided with appreciable drying of the soil. Low rates of N₂O loss were also observed during the first 3 weeks of the study even though the soil was at field capacity (water content 28-30%); however, soil temperature was ≤5 °C and nitrate content $<1 \mu g N g^{-1}$.

The most striking feature of the data in Fig. 1 is that the 250 kg N ha-1 treatment acted as both a source of and a sink for atmospheric N2O. Sink activity as high as 11.6 ng N m⁻² s⁻¹ has been measured, although weekly mean values (Fig. 1) never exceeded 5.8 and were generally between 1.2 and $3.5 \text{ ng N m}^{-2} \text{ s}^{-1}$. The prevailing soil conditions during periods of sink activity were moderate to high (>20%) soil water content, very low nitrate content ($\leq 1~\mu g~N~g^{-1}$) and temperatures above 5-8 °C (Fig. 1). Sink activity was observed before fertilizer application when soil temperature increased above 5 °C. Sink activity resumed 3 weeks after the second fertilizer application and 2 weeks after the third application when soil nitrate content fell to low levels and water content remained

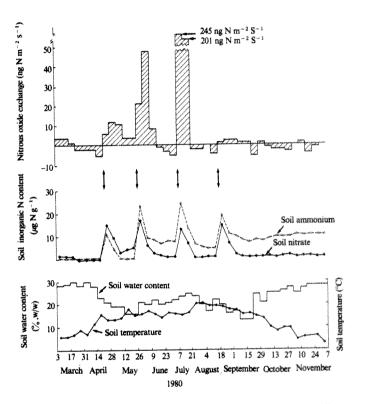

Fig. 1 Nitrous oxide exchange, soil nitrate and ammonium content (0-20 cm), soil moisture content (0-20 cm) and soil temperature (2 cm) in grassland receiving 250 kg N ha⁻¹ yr⁻¹ as ammonium nitrate. Fertilizer was applied in four equal amounts on the dates indicated (\$). The sward was cut and herbage removed immediately before each fertilizer application and on 19 September N2O exchange was measured using a modified version of the soil cover technique described in ref. 28. The cover had a removable lid, enclosed an air volume of 7.5 dm³ and covered an area of 0.075 m². The air flow (500 cm³ min⁻¹) through the cover was allowed to equilibrate with the soil surface for at least 1 h before starting the N2O exchange measurement. N₂O exchange was determined for periods of 3 h by comparing the amount of N₂O in air drawn through the cover with that in an equivalent flow of air drawn from the free atmosphere at the same height as the air entry port for the cover. The rate of air flow used to sweep the cover must equal that used to sample the free atmosphere. Accurate matching of flow rates was achieved using stainless steel needle valves and air flow tubes each of which was calibrated to 500 cm³ min⁻¹ ± 1% using a wet gas flowmeter. The air flow control gave a standard error of ±0.005 p.p.m. (v/v) for 10 simultaneous determinations of an atmospheric N2O concentration of 0.320 p.p.m. The mean atmospheric N2O concentration during the study period was 0.324 ± 0.013 p.p.m. for 160 determinations. A detection limit of 1.2 ng N m $^{-2}$ s $^{-1}$ for N2O exchange was obtained. Measurements of N2O exchange were made on at least 3 days per week between 3 March and 19 September. During periods following fertilizer application or rain, measurements were made on 5 or 6 days per week. After 19 September measurements were made on 2 days per week. To facilitate handling of large numbers of samples, soil nitrate and ammonium content was determined by extraction with 2 M KCl after rapidly drying soils in a forced-air oven at 70 °C. Soil water content was determined gravimetrically on the same samples. Soil nitrate contents determined using this procedure were not significantly different from those determined by extraction of field moist soil. Drying increased ammonium content by 2-4 µg N per g soil.

>20% as a result of persistent rain. Significantly, in a companion treatment receiving 500 kg N ha-1 yr-1 no sink activity was observed—soil nitrate content remained above 2 µg N g throughout the study.

How soil water content affects source or sink activity is illustrated in the 3-week periods following 28 July and 22 September when sink activity ceased as the soil passed through a drying phase. A similar effect was observed in November when the soil passed through periods when its temperature fell below 5 °C. The oscillation between low rates of N₂O loss and sink activity in response to changes in soil temperature continued throughout the winter until the first fertilizer application in mid-March 1981 when significant loss of N₂O resumed.

The unfertilized control strip invariably acted as a sink for N₂O at times when soil water content exceeded 20% (Table 1). Sink activity ceased only when the soil dried to lower water content or when its temperature fell below 5 °C (Table 1; Fig. 1). As with the 250 kg N ha⁻¹ treatment, sink activity was associated with persistently low soil nitrate content, weekly mean and individual values never exceeding 1 µg N g⁻¹ (Table 1).

Measurements made concurrently with those reported in Fig. 1 and Table 1 indicated that denitrification was the major process determining both source and sink activity for N2O in the present study. Loss of N2O was always associated with a larger denitrification loss measured using the C₂H₂-inhibition technique⁸ at other areas of the same plot. Rates of N₂O loss from C₂H₂-treated areas were two to seven times greater than those measured in the absence of C₂H₂ (Fig. 1). Production of N₂O during denitrification in soils is favoured by high nitrate content, temperature conducive to high respiratory oxygen demand, and water contents leading to restricted aeration and the development of anaerobic microsites⁹. Maximum N₂O loss was observed (Fig. 1) when such conditions prevailed. During periods of sink activity there was also a small net loss of N (generally <12 ng N m⁻² s⁻¹) from C_2H_2 -treated areas. Sink activity was only observed in conditions conducive to microbial reduction of N2O; namely when the nitrate available for reduction during denitrification was essentially exhausted and when reductive stress was placed on the system^{10,11} with soil water content at or above 20% and temperatures above 5-8 °C.

Some workers have found that N2O loss may also arise from nitrification, particularly in calcareous soils with high ammonium content¹². Following the application of fertilizer on 7 July 1980, the rates of N₂O loss measured 12-24 h after termination of C₂H₂ treatment were not significantly different (99% confidence level; six replicates) from those measured in areas that had not been treated with C₂H₂ (six replicates). For example, on 11 July, areas treated with C₂H₂ yielded N₂O at

 $^{^*}$ <+1.2, >-1.2 ng N m⁻² s⁻¹.

 $493 \pm 135 \text{ ng N m}^{-2} \text{ s}^{-1}$. Other areas that had received C_2H_2 treatment 16 h previously yielded N_2O at 325 ± 24 ng N m⁻² s⁻¹ a rate not significantly different from that $(332\pm58~{\rm ng}~N~m^{-2}~s^{-1})$ for areas that had never been treated with C_2H_2 . As low concentrations of C_2H_2 also inhibit nitrification, an effect which persists for several days after removal of C₂H₂ (ref. 13), it seems unlikely that nitrification made an appreciable contribution to N₂O loss from this non-calcareous soil even during the periods of high soil ammonium content following fertilizer applications.

The rates of N₂O loss observed in the present study are within a similar range to that reported¹⁴⁻²¹ for arable and grassland systems, although in only one such study¹⁷ has sink activity been observed. Nevertheless, there is direct²² and indirect^{10,23,24} evidence that soil may act as a sink for atmospheric N₂O. Conditions favourable to sink activity 10,11 may be expected to develop rapidly in moist to wet soils under grass. The dense root mass characteristic of such soils rapidly depletes nitrate in the soil solution and provides potential for appreciable oxygen demand as a result of root respiration and microbial degradation of organic matter. The observation that sink activity rarely exceeded mean weekly rates of $5.8~\rm ng~N~m^{-2}~s^{-1}$ (Fig. 1; Table 1), irrespective of fertilizer application, suggests that sink activity was limited more by the ease of diffusion of N2O from the atmosphere to zones of N₂O depletion within the soil, than by the potential for N_2O reduction per se.

In the present study, $\sim 1.3\%$ of the fertilizer N applied at a rate of 250 kg N ha⁻¹ yr⁻¹ was lost between 3 March 1980 and 2 March 1981. This proportion is in reasonable agreement with the estimate made by the Council for Agricultural Science and Technology³ for annual N₂O loss from fertilized land but is at least one order of magnitude lower than that implied by other models of N₂O dynamics⁴⁻⁶. The proportion of fertilizer N lost as N₂O in the present study is of the same order as that observed during complete cropping seasons elsewhere 14-16,18

The fact that sink activity for N₂O (Fig. 1; Table 1) was associated with a small net loss of N arising from denitrification (discussed above) suggests that denitrification in soils with low concentrations of inorganic N, despite high total N content, contributes little if any N₂O to the atmosphere. However, additional N₂O may be lost following conversion of grassland to arable production when mineralization of stored fertilizerderived N may produce elevated concentrations of inorganic N. Nevertheless, even in agricultural systems assumed to be at equilibrium with respect to reserves of soil N, losses of N as N₂O were never greater than 5-7% of the fertilizer N applied even at rates as high as 680 kg N ha⁻¹ yr⁻¹ (ref. 15).

The present and previous studies¹⁴⁻²⁰ suggest that forecasts of

N₂O losses from industrially fixed N may have been appreciably overestimated. Furthermore, sink activity for N₂O has now been observed in grassland soils (present study), arable soils¹⁷ and lake, estuarine and marine sediments²⁵⁻²⁷. The indications that N₂O source strength from industrially fixed N may have been overestimated suggest that the sink strength of the pedosphere and hydrosphere for atmospheric N₂O may be more significant than previously assumed.

I thank Drs D. Barraclough and T. R. Owen for cooperation in the use of field facilities, also A. W. Bristow and J. E. McNeill for technical assistance and Dr L. H. P. Jones for helpful comments. The Grassland Research Institute is financed through the Agricultural Research Council.

Pseudogenes as a paradigm of neutral evolution

Wen-Hsiung Li, Takashi Gojobori & Masatoshi Nei

Center for Demographic and Population Genetics. The University of Texas at Houston, Houston, Texas 77025, USA

On the neutral mutation hypothesis 1-3, the rate of nucleotide substitution is expected to be higher for functionally less important genes or parts of genes than for functionally more important genes, as the latter would be subject to stronger purifying (negative) selection²⁻⁴. On the other hand, selectionists believe that most nucleotide substitutions are caused by positive darwinian selection^{5,6}, in which case the rate of nucleotide substitution in functionally unimportant genes or parts of genes^{2,7} is expected to be relatively lower because the mutations in these regions of DNA would not produce any significant selective advantages. Kimura⁸ and Jukes⁹ have argued that the higher substitution rate observed at the third positions of codons than at the first two positions supports the neutral mutation hypothesis, as most third-position substitutions are synonymous and do not change the amino acids encoded, although others^{5,10} have discussed the possibility that third-position substitutions are subject to positive darwinian selection. Recently, Kimura¹ noted that the mouse globin pseudogene, $\psi \alpha 3$, evolved faster than the normal mouse $\alpha 1$ gene, although he did not compute the substitution rate. Here, we present a method of computing the rate of nucleotide substitution for pseudogenes, and report that the three recently discovered pseudogenes show an extremely high rate of nucleotide substitution. As these pseudogenes apparently have no function, this finding strongly supports the neutral mutation hypothesis.

A pseudogene is a DNA segment with high homology with a functional gene but containing nucleotide changes such as frameshift and nonsense mutations that prevent its expression. (Some authors 12 have argued possible functions of pseudogenes, but their arguments are not substantiated.) Pseudogenes seem to have been produced by the nonfunctionalization of duplicate genes. A complete nucleotide sequence is now available for three pseudogenes (mouse $\psi \alpha 3$, human $\psi \alpha 1$ and rabbit $\psi \beta 2$ in the globin gene families)¹³⁻¹⁵. Figure 1 shows a probable evolutionary scheme for mouse pseudogene $\psi \alpha 3$ ($M\psi \alpha 3$), mouse functional gene $\alpha 1 (M\alpha 1)^{16}$ and rabbit functional gene $\alpha (R\alpha)^{16}$ in which O denotes the point of duplication leading to $M\psi\alpha$ 3 and $M\alpha 1$.

Let d_{ABi} , d_{ACi} and d_{BCi} be the numbers of nucleotide substitutions per site at the *i*th position of codons (i = 1, 2 or 3) between $M\psi\alpha$ 3 and $M\alpha$ 1, between $M\psi\alpha$ 3 and $R\alpha$, and between $M\alpha$ 1 and $R\alpha$, respectively, and let l_i , m_i and n_i be the numbers of nucleotide substitutions per site between O and $M\psi\alpha$ 3, between O and $M\alpha$ and between O and $R\alpha$, respectively. We then have $d_{ABi} = l_i + m_i$, $d_{ACi} = l_i + n_i$, $d_{BCi} = m_i + n_i$. Therefore, l_i , m_i and n_i can be estimated by

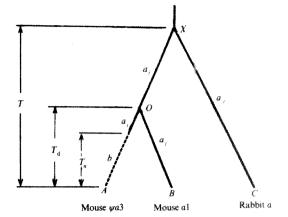

Fig. 1 Plausible phylogenetic tree for mouse $\psi \alpha 3$, mouse $\alpha 1$ and rabbit a. T denotes the divergence time between mouse and rabbit, T_d the time since duplication of mouse $\psi \alpha 3$ and $\alpha 1$, and T_n the time since nonfunctionalization of mouse $\psi \alpha 3$. a, denotes the rate of nucleotide substitution per site per year at the ith position of codons in the normal globin genes and b the rate of substitution for mouse pseudogene $\psi \alpha 3$. The proportion of nucleotide differences is 51/354 between mouse $\psi \alpha 3$ and $\alpha 1, 84/423$ between mouse $\alpha 1$ and rabbit α , and 91/354 between mouse $\psi \alpha 3$ and rabbit α (see Table 1)

$$l_i = (d_{ABi} + d_{ACi} - d_{Bci})/2 \tag{1a}$$

$$m_i = (d_{ABi} - d_{ACi} + d_{BCi})/2$$
 (1b)

$$n_i = (-d_{ABi} + d_{ACi} + d_{BCi})/2$$
 (1c)

Pseudogenes often have deletions and insertions. nucleotides involved in these changes should be eliminated from data analysis, because we are interested only in nucleotide substitution. This can be done by aligning a pseudogene with its homologous functional gene for the coding regions. In our study we followed the alignments given by the original authors 13-15. In mouse $\psi \alpha 3$, however, we excluded the 30 nucleotides that have been aligned with the nucleotides starting from positions 91 to 120 of the functional mouse $\alpha 1$. In this region there were 21 mismatches, including one sequence of 8 mismatches and another of 7 mismatches. This pattern was very different from that of other parts of the gene and probably occurred through insertion rather than nucleotide substitution. At any rate, after these alignments, we computed the proportion of different nucleotides between homologous genes (Table 1), and from this proportion (p) the total number of nucleotide substitutions per site (d_{ABi}, d_{ACi}) or d_{BCi} was estimated by $d = -(3/4) \ln [1 - (4/3)p]$ (ref. 18). For computing d we also

used Kimura's formula¹¹, but the values were not much different.

In Fig. 1 we used rabbit α as a third gene, but human α 1 or α 2 can also be used for this purpose, as their nucleotide sequences are known^{14,19}. We have therefore computed the d values for each of these genes and used the averages of the values to compute l_i , m_i and n_i (Table 2) and the other quantities to be given later. Table 2 also includes the results for human pseudogene $\psi \alpha$ 1 and rabbit pseudogene $\psi \beta$ 2. It is seen that in the evolution of functional genes (between O and B and between O and C), the third position of codons changes several times faster than the first two positions, which evolve at almost the same rate, but in the line leading to a pseudogene (between O and A) the rates of change for the three positions are about the same and are higher than those between O and B. Clearly, pseudogenes evolve faster than functional genes.

The above computation does not give the substitution rate for pseudogenes. To compute this rate, we must know the time since nonfunctionalization of a pseudogene. Let us again use the three genes in Fig. 1 as an example. In this figure the time (T) since divergence between $M\alpha 1$ and $R\alpha$ is known to be about 80 Myr, but the time (T_a) since duplication of $M\psi\alpha 3$ and $M\alpha 1$ and the time (T_n) since nonfunctionalization of $M\psi\alpha 3$ must be estimated. We estimate these times and the rates of nucleotide substitution for the functional genes and pseudogenes simultaneously. Let a_1 , a_2 and a_3 be the rates of nucleotide substitution per site per year at the first, second and third positions of codons in the functional genes, respectively. Once a gene becomes nonfunctional, the rate of nucleotide substitution is expected to be the same for all of the three positions, and we denote the rate by b. From Fig. 1 we obtain

$$d_{ABi} = 2a_i T_d + (b - a_i) T_n \tag{2}$$

$$d_{ACi} = 2a_i T + (b - a_i) T_n \tag{3}$$

$$d_{BCi} = 2a_i T (4)$$

As we know T, a_i can be estimated by $d_{BCi}/(2T)$. We also note

$$y_i \equiv d_{ACi} - d_{BCi} = bT_n - a_i T_n \tag{5}$$

Therefore, from equations (2) and (5), T_d can be estimated by $(\sum d_{ABi} - \sum y_i)/(2\sum a_i)$, where \sum stands for the summation over *i*.

To estimate T_n and b, we can use equation (5) and apply the standard least-squares method, as there are two unknowns and three equations. However, note that essentially the same results are obtained by the following simple formulae

$$T_n = (y_{12} - y_3)/(a_3 - a_{12}) \tag{6}$$

$$b = (a_3 y_{12} - a_{12} y_3) / (y_{12} - y_3)$$
 (7)

where $y_{12} = (y_1 + y_2)/2$ and $a_{12} = (a_1 + a_2)/2$. Expressing equations (6) and (7) in terms of l_i , m_i and n_i , we have obtained approximate formulae for the standard errors of T_n and b (not

shown). In practice, T_n obtained by equation (6) may be larger than T_d . In this case, we set $T_d = T_n$ because by definition $T_n \le T_d$. When $T_n = T_d$, equation (5) gives $b = (\sum a_i T_d + \sum y_i)/T_d$.

Table 3 shows the results for a_i , T_d , T_n and b. Interestingly, each of a_1 , a_2 and a_3 is nearly the same for the three groups of genes studied. However, a_3 is about four times larger than a_1 and a_2 . These estimates are similar to those obtained by Kimura⁸ and Jukes⁹ and support these authors' conclusion that the rate of synonymous substitution is higher than the rate of non-synonymous substitution. The b values in Table 2 indicate that the rate of nucleotide substitution in pseudogenes is even higher than the rate at the third positions of codons in the functional genes. The average rate of 4.6×10^{-9} is one of the highest rates of nucleotide substitutions so far estimated. Only two other estimates are comparable with this value. One is the rate (7.0×10^{-9}) for the synonymous substitution in the Cpeptide region of the preproinsulin genes²⁰, and the other is that (6.2×10^{-9}) estimated from amino acid sequence data for the rapidly evolving residues of fibrinopeptides²¹. These peptides are believed to have no biological function except for holding other polypeptides that will later form a protein. Our finding clearly indicates that functionally less important genes evolve faster than functionally more important genes, and thus supports the neutral mutation hypothesis. Furthermore, comparison of a_3 and b suggests that the third-position substitutions in the globin genes are subject to purifying selection.

Our estimate (T_d) of the time since gene duplication is 27 Myr for mouse $\psi \alpha 3$ and $\alpha 1$, 49 Myr for human $\psi \alpha 1$ and α , and 44 Myr for rabbit $\psi \beta 2$ and $\beta 1$. These estimates are somewhat smaller than those (30, 60, 55 Myr, respectively) obtained by Maniatis and his associates ^{14,15}, mainly because these authors assumed that the substitution rate for the pseudogenes is the same as that for the synonymous changes in functional globin genes. This assumption seems to be incorrect, as the former rate is about twice as great as the latter rate in our study. If our estimates of the times of gene duplication are reliable, the mouse $\psi \alpha 3$ diverged from the $\alpha 1$ gene about 27 Myr ago and became a pseudogene about 4 Myr later. On the other hand, the human $\psi \alpha 1$ was duplicated from the α gene about 49 Myr ago and became nonfunctional about 4 Myr later. The rabbit $\psi \beta 2$ gene became nonfunctional almost immediately after it was duplicated from the $\beta 1$ gene about 44 Myr ago.

We have studied the evolutionary changes of pseudogenes as a paradigm of neutral evolution because in these genes the fate of new mutations in a population is determined almost entirely by genetic drift under the neutral mutation hypothesis. In practice, most genes in the genome would have some biological function and thus be subject to a varying degree of purifying selection. Even in these genes, however, there may be a large

 a_1 , a_2 and a_3 refer to the rates of nucleotide substitutions for the first, second and third positions of codons in the functional genes, respectively. * We were unable to compute a proper standard error for this estimate, because T_n was assumed to be equal to T_d (see text).

number of mutant forms (nucleotide sequences) that are equally functional and fit in adaptation. All these mutant forms will be a source of neutral evolution.

This work was supported by grants from the NIH and NSF. Note added in proof: After submission of this paper, we learned that Miyata and Yasunaga²² estimated the rate of nucleotide substitution for mouse $\psi \alpha 3$. Their estimate is higher than ours, because they did not exclude the middle part of the sequence.

Gait and the energetics of locomotion in horses

Donald F. Hoyt* & C. Richard Taylor

Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA

It seems reasonable that quadrupeds should change gait from a walk to a trot to a gallop in such a way as to minimize their energy consumption, as human beings are known to change from a walk to a run at a particular speed (2.4 m s^{-1}) below which walking requires less energy than running and above which the opposite is true. Thus by changing gait, human beings keep the energy cost of locomotion to a minimum as their speed increases. One reason this relation holds is that in humans, metabolic rate increases curvilinearly with walking speed¹. If metabolism were a curvilinear function of speed within each of the gaits used by quadrupeds, it would support the hypothesis that they also change gait to minimize energetic cost. There is an old controversy about whether metabolic rate increases linearly or curvilinearly in running humans^{1,2} but all previous reports have suggested that metabolic rate increases linearly with speed in quadrupeds. Extended gaits were an important experimental tool in the study of human gait changes; thus we have trained three small horses (110-170 kg) to walk, trot and gallop on a motorized treadmill, and to extend their gaits on command. We report here that, using measurements of rates of oxygen consumption as an indicator of rates of energy consumption, we have confirmed that the natural gait at any speed indeed entails the smallest possible energy expenditure.

Rate of oxygen consumption increased curvilinearly with speed for walking and trotting (Fig. 1). We were unable to obtain sufficiently high galloping speeds to evaluate whether rate of oxygen consumption also increased curvilinearly during a gallop. Transitions between gaits normally occurred at the speeds where the curves intersected and oxygen consumption was the same for the two gaits. When the gaits were extended beyond their normal range of speeds, oxygen consumption was higher in the extended gait than in that which the animal would normally be using. For example, horse B normally walked at a speed of 1.25 m s⁻¹. When trotting at 1.25 m s⁻¹, the rate of oxygen consumption was 1.5 times that measured during a walk.

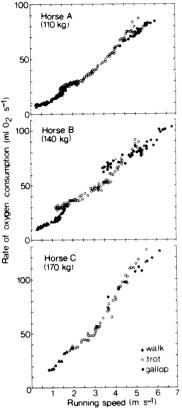

Fig. 1 Steady-state rate of oxygen consumption as a function of speed for a walk, a trot and a gallon in three small horses. The horses normally changed from walk to trot, or trot to gallop at the point where rate of oxygen consumption was the same in the two gaits. We were able to train the animals to extend their gaits to speeds where they would have normally used a different gait. The data from the extended gaits accentuated the curvilinear nature of the relationship between rate of oxygen consumption and speed within a gait. Linear regression provided a good fit of the data if we omitted measurements made when animals used extended gaits. The least-squares regressions and coefficients of determination (r^2) are: horse A, $V_{\rm O2} = -1.22 + 14.4 \cdot v$, $r^2 = 0.99$; B, $V_{\rm O2} = 2.68 + 15.0 \cdot v$, $r^2 = 0.98$; C, $V_{\rm O2} = -8.61 + 22.2 \cdot v$, $r^2 = 0.98$ where $V_{\rm O2}$ is ml O₂ s⁻¹ and v is velocity in m s⁻¹ We considered that a steady-state oxygen consumption was achieved when we recorded a constant rate of oxygen consumption for at least 5 min. At the speeds used here, steady-state was never reached during the first 6 min of measurement, thus all measurements at a given speed were made for at least 11 min. During these measurements, air temperature averaged 21 °C and air speed was approximately matched to tread speed. The animals were loosefitting masks which allowed capture of all expired gases. Rates of gas flow through the mask were varied from 1501 min⁻¹ to 1,3001 min⁻¹ during different runs to produce excurrent oxygen concentrations between 20.6 and 20.1%. During the runs the laboratory was ventilated by a large fan and ambient oxygen concentrations remained constant at ~20.9%. Previous studies of horses, including pony B of ref. 4, found no change in blood lactate levels when animals ran on a level treadmill at speeds up to 10 m s⁻¹; therefore we conclude that there is no anaerobic contribution to energy consumption at speeds $<7 \,\mathrm{m\,s^{-1}}$.

There was a speed for each gait where the amount of oxygen used to move a given distance (rate of exygen consumption divided by speed) reached a minimum value (Fig. 2). This speed represents one that is energetically optimal for each gait. The minimum values were about the same for a walk, a trot and a gallop. Therefore, the amount of energy consumed by a horse to move a given distance is the same at these optimal speeds.

To determine whether animals normally moved at energetically optimal speeds, we measured speeds and gaits of a horse as it moved freely over a marked grid. We found that the horse selected speeds within each gait around the energetically optimal speed (Fig. 2). Pennycuick³ has observed that migrating African animals use only a restricted range of speeds within each gait. This suggests that these animals might also be using an energetically optimal speed for each gait.

Linear regression of the data provides a reasonable fit to the relationship between oxygen consumption and speed if one disregards the data obtained when the animals had abnormally extended gaits $(r^2 = 0.98)$. In fact the curvilinear relationship

^{*}To whom correspondence should be addressed at: Department of Biological Sciences, California State Polytechnic University, Pomona, California 91768, USA.

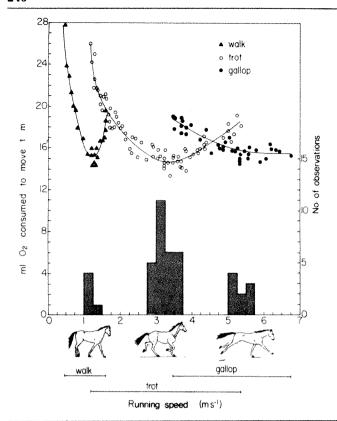

Fig. 2 The oxygen cost to move a unit distance (rate of oxygen consumption divided by speed, calculated from data in Fig. 1) declined to a minimum and then increased with increasing speed in a walk and trot. It also declines to a minimum in a gallop, but we were unable to obtain sufficiently high galloping speeds to observe any increase at high galloning speed if it occurred. The minimum oxygen cost to move a unit distance was almost the same in all three gaits. The histogram shows gaits where horse B was allowed to select her own speed while running on the ground. She chose three speeds which coincided with the energetically optimal speed for each gait. On a motorized treadmill, the animal must move at the speed of the tread, but note that when running on the ground, there were ranges of speeds which the animal never used for any sustained period.

can only be observed when great care is taken to avoid any source of variability in the data. Therefore, it seems useful to continue to use a single linear relationship between rate of oxygen consumption and speed for comparative studies of energetics of locomotion.

We conclude that horses, like humans, change gait and select speed within a gait in a manner that minimizes energy consumption. Observations of speeds used by migrating African animals³ suggest that this finding may also apply generally to terrestrial animals.

Gene expression in visna virus infection in sheep

Michel Brahic, Linda Stowring, Peter Ventura & Ashlev T. Haase

Infectious Disease Section, Veterans Administration Medical Center and Departments of Medicine and Microbiology, University of California, San Francisco, San Francisco, California 94121, USA

Visna is a slow degenerative disease of the central nervous system (CNS) of sheep caused by a nontumorigenic retrovirus'. During the course of this disease, visna virus establishes a persistent infection of the CNS, lung and haematopoietic system, despite a specific humoral and cellular immune response. We have studied visna virus life cycle at the single-cell level in choroid plexus of experimentally infected animals, using a very sensitive and quantitative in situ hybridization assay2. We report here that although proviral DNA is synthesized in significant amounts, its expression is blocked at the transcriptional level. This restriction of proviral DNA transcription offers an explanation for the slowness of the disease and the persistence of the infection.

Two aspects of visna infection are relevant to the question of slowness and persistence. First, the virus is predominantly cellassociated, especially in the blood; second, the amount of virus present at any time during the course of the disease is minimal³. This limitation in virus growth is not a consequence of the immune response because it is observed before virus-specific antibodies can be detected, and because immunosuppression of infected animals does not lead to a higher titre of virus4. Restricted virus replication therefore seems to be an intrinsic property of the virus-cell interaction in the tissues of the animal (in vivo). This in vivo situation is in sharp contrast to virus replication in ovine cells grown in vitro, where the virus grows to high titre and causes a characteristic cytopathic effect that culminates in cell death 48-72 h after infection.

The first clue to the mechanism of restriction of replication in vivo was revealed by studies which showed that proviral DNA can be detected by in situ hybridization in a significant fraction

of the cells in the choroid plexus, but that only an occasional cell contains the major structural viral polypeptide p30 as detected by immunofluorescence⁵. This restriction of proviral DNA expression provided an explanation for the persistence of the infection: the immune defence mechanisms are unable to eradicate the infection because the virus persists intracellularly in cells that do not express viral antigens. Therefore, an understanding of the mechanism of restriction of viral gene expression is central to the study of visna pathogenesis.

We chose to study viral replication in the choroid plexus because histopathological lesions of visna always predominate in this tissue as well as in the periventricular areas of the brain³, and because persistent infection of the choroid plexus has been clearly documented by isolation studies³. Although it is a relatively simple structure, the choroid plexus consists of various cell types (cuboidal epithelium cells, fibroblasts, endothelial cells and smooth muscle cells) interspersed with large numbers of inflammatory cells characteristic of visna lesions. Because of this complex setting and the possibility of local variations in the extent of infection, virus replication must be studied at the single-cell level. Viral protein synthesis was assessed by immunofluorescence using an indirect assay and the labelled avidin-biotin method of detection⁶. Virus nucleic acids were quantitated in single cells in histological sections by in situ hybridization² modified for the detection of proviral DNA as described in Fig. 1 legend. This assay will detect 1 to 2 copies of viral RNA and 10 copies of proviral DNA per cell after three weeks of autoradiographic exposure (10 grains per cell above background).

Three American lambs were inoculated intracranially with 10° plaque-forming units (PFU) of visna virus strain 1514. The inoculum (1 ml) was deposited in the vicinity of the lateral ventricule. A large inoculum was chosen to infect a maximum number of cells at the site of inoculation. The animals were killed between 7 and 15 days after inoculation, and the choroid plexi removed. Inflammatory lesions typical of visna were observed in all cases. A portion of choroid plexus was frozen, subsequently sectioned in a cryomicrotome and assayed for viral nucleic acids and proteins. Examples of the results obtained by in situ hybridization are shown in Fig. 2. Proviral DNA and viral RNA were readily detected in these sections. In all cases where the cells could be unambiguously identified, viral nucleic acids were present only in cuboidal epithelium cells; they were not found in vessels, connective tissue cells or inflammatory mononuclear cells.

The fraction of choroid plexus cells carrying proviral DNA and viral RNA was determined (Table 1); values range between

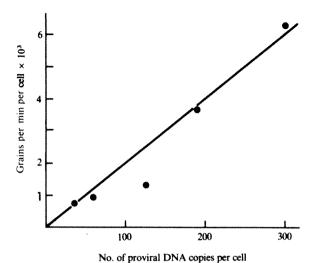

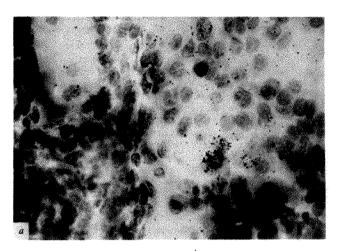

Fig. 1 Relationship between the amount of proviral DNA per cell and the number of autoradiographic grains developed after in situ hybridization. Sheep choroid plexus cells grown in vitro were infected with 3 PFU of visna virus per cell. At various times after infection (10, 14, 23, 48 and 72 h), the cells were collected and subjected in parallel to in situ hybridization and determination of proviral DNA content by liquid hybridization9. For in situ hybridization microscope slides were treated with bovine serum albumin, Ficoll and polyvinyl pyrrolidone as described elsewhere² cells were deposited on treated slides using a cytocentrifuge, air dried for a few minutes and fixed for 4 min at -20°C in a mixture of methanol and acetone (1:2, v/v). The slides were treated with HCl, heat and proteinase K as described elsewhere². RNA was eliminated by treating the slides for 30 min at 37°C with 100 µg ml of RNase A and 10 units ml⁻¹ of RNase T_1 in $2 \times SSC$ (0.3 M NaCl, 0.03 M Na citrate, pH 7.5), followed by two washes in $2 \times SSC$ and dehydration in graded ethanol. To ensure maximal retention of viral DNA, the slides were refixed in 5% formaldehyde at room temperature for 2 h, then washed twice in 2×SSC and dehydrated in graded ethanol. DNA denaturation was achieved at 65°C for 15 min in 95% deionized formamide, 0.1×SSC followed by quenching in ice-cold 0.1×SSC. The slides were washed twice more in 0.1 × SSC and dehydrated in graded ethanol. Hybridization in situ was as described elsewhere² except that the concentration of cDNA was 0.8 ng μl^{-1} . Washing of the slides, dipping in NTB-3 Kodak emulsion and exposure was as described elsewhere². The slides were exposed for 3 weeks (10-h infected cells), 11 days (14 and 24-h infected cells) and 48 h (48 and 72-h infected cells). An average of 1,500 grains were counted for each slide; the extent of in situ hybridization was expressed as number of grains per min of exposure time per nucleus. Uninfected cells were processed in parallel for the determination of background. The background was 1.7×10^{-4} grains per min per nucleus.

1 and 3%. For a given animal the same fraction of cells contained proviral DNA and viral RNA. Table 1 also shows averaged values of proviral DNA and viral RNA content per cell. The distribution of values for individual cells is shown in Fig. 3. On average, infected cells contained 60–70 copies of proviral DNA per cell. Although the values are spread over a relatively broad range, cells containing levels of proviral DNA comparable to those observed at the end of the permissive cycle (200–300 copies per cell (B. Traynor, personal communication)) were extremely rare (Fig. 3). The average content of viral RNA in the tissues varied between 100 and 180 copies of 35S RNA genome equivalents, and the distribution of RNA content among cells was relatively narrow, with almost no cells containing more than 500 copies. These values are almost two orders of magnitude below the level of RNA synthesis observed at the end

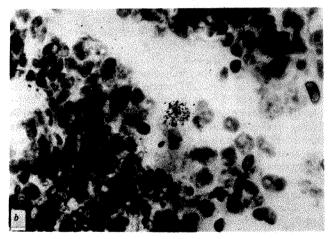

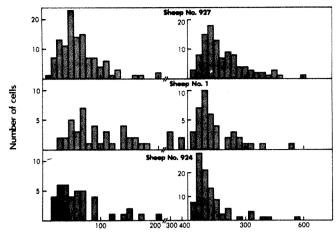

Fig. 2 Detection of proviral DNA (a) and viral RNA (b) in sections of choroid plexus from experimentally infected sheep. The figure shows one representative field in each case. Exposure times were 3 weeks (a) and 48 h (b).

Table 1 Numbers of choroid plexus cells carrying proviral DNA and viral RNA

		Viral DNA No. of positive cells	Viral RNA No. of positive cells	Avera	% Of cells		
Sheep no.	Days after inoculation	Total no. of cells (%)	Total no. of cells (%)	Viral DNA	Viral RNA	containing viral proteins	
927	7	$142/1.5 \times 10^4 (0.9)$	$325/2.5 \times 10^4 (1.3)$	61	177	0	
1	10	$156/1.5 \times 10^4 (1.0)$	$394/2.5 \times 10^4 (1.6)$	74	129	0.0025	
924	15	$429/1.5 \times 10^4 (2.8)$	$684/2.5 \times 10^4 (2.7)$	61	105	0	

The number of cells positive for viral DNA was measured after 6 weeks of autoradiographic exposure, and for viral RNA was measured after 3 weeks of exposure. Total number of cells was estimated from the number of cells within the area of a reticle and the ratio of the area of the reticle to that of the section. Percentage of cells containing yiral proteins was determined by immunofluorescence using anti-p30 serum.

* One copy corresponds to a MW of 6×10^6 double-stranded provinal DNA or 3×10^6 single-stranded viral RNA.

Proviral DNA (copies per cell)

Viral RNA (copies per cell)

Fig. 3 Distribution of proviral DNA and viral RNA content among choroid plexus cells in vivo. The choroid plexus of three experimentally infected animals were examined by in situ hybridization. The autoradiographic exposure times were 3 weeks and 48 h for proviral DNA and viral RNA detection, respectively. In each case a representative section (~12 mm²) was systematically scanned under the microscope at a magnification of ×1,000. The number of grains per cell was counted for each positive cell. The number of genome copies per cell was determined from calibration curves (see Fig. 1 and ref. 2). The histograms were constructed by grouping copy numbers to the nearest multiple of 10.

of a permissive cycle (=10,000 copies per cell⁷). Hybridization to proviral DNA was totally dependent on denaturation and was sensitive to pretreatment with DNase, therefore ruling out the possibility that the hybrids observed in the DNA assay were due to residual viral RNA. Immunofluorescence was carried out on subjacent sections of choroid plexus from the same animals; no convincingly positive cells were detected in two animals. A positive cell was occasionally found in the choroid plexus of sheep no. 1 (Table 1).

This quantitative analysis of viral replication in the choroid plexus demonstrates the following: (1) visna virus infects cuboidal epithelial cells. (2) Despite a relatively large inoculum deposited in the vicinity of the choroid plexus, the proportion of cuboidal choroid plexus cells infected is relatively low (=1%). (3) The level of viral RNA expressed in these cells is minimal. Infected cells constitute a fairly homogeneous population of cells containing 100-200 viral genome equivalents. In this respect these cells are similar to in vitro infected permissive cells arrested at a very early stage of the viral life cycle. Although they contain relatively high levels of proviral DNA (60-70 copies per cell), their RNA content is about two orders of magnitude lower than during a permissive viral replication cycle. This shows that the restriction of proviral DNA expression is regulated, at least in part, at the transcriptional level. (4) Choroid plexus cells do not contain viral structural proteins as determined by immunofluorescence.

These results represent a new step in the understanding of visna pathogenesis. Two characteristic aspects of this disease are the low level of virus expression and the persistence of the infection for long periods of time in spite of an immune response. Here we have documented the restriction of virus expression at the single-cell level. Minimal virus production is due to the limitation of the infection to a small fraction of the cells and the existence in these cells of a block at the level of proviral DNA transcription. We propose that restricted proviral DNA expression plays a part in two aspects of visna pathogenesis. First, it provides a damping mechanism which prevents the rapid spread of the infection and its expression as an acute disease and also limits the damage caused by viral replication to individual cells. (Indeed cell necrosis is conspicuously absent in visna, particularly during the early incubation period⁸.) Second, it allows the virus to persist: cells which are not killed as a result of the infection and which do not express viral antigens at their

surface provide the virus with a site where it can persist without being detected and eradicated by the immune defence mechanisms.

Apparent reversion of stable in vitro genetic markers detected in tumour cells from spontaneous metastases

J. Dennis, T. Donaghue, M. Florian & R. S. Kerbel

Cancer Research Laboratories, Department of Pathology, Queen's University, Kingston, Ontario, Canada K7L 3N6

The evolution towards more aggressive and autonomous behaviour of many cancerous tumours, often referred to as tumour progression¹, is thought to stem from the development of heterogeneity within the tumour cell population, combined with the continuous selection of progressively more malignant cellular phenotypes^{2,3}. During the course of the disease, the tumour cells show multiple phenotypic changes in a stepwise, but apparently random fashion, becoming more anaplastic, increasingly independent of growth controls and more metastatic4. Several laboratories, including our own, have analysed aspects of tumour heterogeneity and cancer metastasis by selecting and studying the properties of lectin-resistant (Lec^R) membrane mutant tumour sublines⁵⁻⁸; in a few cases, such variants have been claimed to be less tumorigenic^{5,6} or metastatic^{7,8} than the parental cells from which they were derived. We have attempted to study the factors involved in the reestablishment of tumour heterogeneity by monitoring the stability in vivo of Lec^R phenotypes of metastatic tumour cells after injection of cloned Lec^R tumour cells. We now report that spontaneous metastases arising after a subcutaneous (s.c.) injection of cells from variant tumour lines selected from a highly metastatic DBA/2 mouse tumour known as MDAY-D29, and which were stably resistant in tissue culture to wheat germ agglutinin (WGA), no longer carry the WGA-resistant (WGAR) phenotype. The results demonstrate that WGA tumour cells do not metastasize, but rather, 'revertants' for the WGAR phenotype, which presumably were generated in vivo after injection, were the cells actually capable of metastatic

The cloned WGAR variant subline MDW4 was selected from the parental MDAY-D2 tumour line by its ability to grow in normally toxic concentrations (for example, 20-50 µg ml⁻¹) of WGA⁵. We have previously shown that MDW4 carries a second phenotypic marker-a deficiency of fucose salvage (fucose salvage caused by a block in the conversion of fucose-1-P to GDP-fucose⁸. These phenotypes seemed to be remarkably stable in MDW4 cells maintained in tissue culture for more than 2.5 yr (Fig. 1). A second variant cell line, MDOW-2b, was sequentially selected for its ability to grow in high concentrations of the toxic membrane-active drug ouabain⁹ (3 mM)

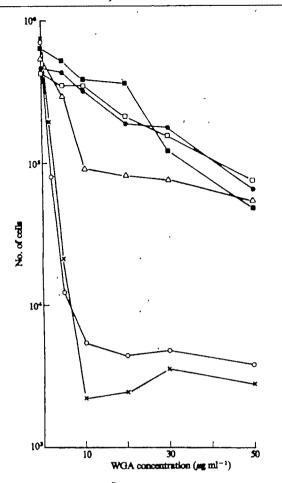

Fig. 1 Stability of the WGA[®] phenotype of the MDW4 tumour clone maintained in tissue culture. Tumour cells were grown in tissue culture in α-MEM (Flow) plus 10% fetal calf serum with subculturing every 3–5 days. The variant was periodically tested for the ability to grow in the presence of WGA; Δ, 10 July 1978; ∰, 6 December 1978; ∭, 10 June 1980; □, 1 October 1980. MDW4 cells were seeded at 3×10³ cells mi⁻¹ in the presence of 0, 2, 5, 10, 20, 30 and 50 μg mi⁻¹ WGA and were grown in ethn until those seeded in the absence of WGA had reached confluence (7–9 days), after which cell numbers were determined in each culture. The revertant, WGA-sensitive (WGA[®]) phenotype of the tumour lines obtained from metastasses and maintained in tissue culture also remained unchanged for the reverted phenotypes after more than 6 months MDW4-22a cells were tested on 22 August 1980 (O) and again on 10 January 1981 (×) The WGA[®] profile of the parental MDAY-D2 cells is shown in Fig. 2, and has also been described previously[§].

and WGA (20 µg ml⁻¹). MDOW-2b did not possess the fucose salvage⁻ phenotype.

As reported previously⁸, WGA^R variants of MDAY-D2 grew and metastasized in an altered way in the syngeneic DBA/2 host. Thus, a s.c. injection of 10³ MDAY-D2 tumour cells produced visible foci of tumour growth in the liver within 2 weeks of injection. In contrast, no liver metastases were evident 2 weeks after a s.c. injection of 105 cells of either MDW4 or MDOW-2b. The number of metastatic nodules, at death, in the livers of mice which had received 10⁵ MDW4 cells s.c. ranged from 0 to 90, whereas mice which died after injection with the same dose of MDAY-D2 cells had almost complete liver replacement with tumour tissue (that is, the number of tumour foci were excessive and not discrete, and therefore not easily counted). An intravenous (i.v.) injection of 103 MDW4 cells results in no tumour takes, whereas i.v. injection of as few as 10 MDAY-D2 cells results in widespread metastases, similar to that observed after s.c. injections. Mice succumbed to the WGAR variants in ~60 days, while the parental tumour MDAY-D2 killed the mice in 35 days (Table 1). We concluded from these results that the WGAR variants, although still malignant, were less so than the parental MDAY-D2 tumour.

Due to the potential ability of tumour cells to change phenotypes and become progressively more malignant in animals¹⁰, it

was not immediately clear whether the few metastases produced by a s.c. injection of the WGAR variants was indicative of an inherently less metastatic tumour line, or of an essentially non-metastatic line which, as a result of the generation and selection of more malignant variants in vivo, showed limited metastasis of these new variants. If ouabain-resistant (Oua"), WGAR and/or fucose salvage phenotypes were related to a reduction in the metastatic potential of the tumour cells, then from the first hypothesis we could predict that metastases would retain the same phenotypes as the injected cells. Conversely, the latter hypothesis would predict that metastases would show a high incidence of revertant phenotypes. To examine this question, solid tumours at the site of injection and individual spontaneous metastases from DBA/2 mice which had been injected with either MDW4 or MDOW-2b cells were removed and re-established as tissue culture lines. The tumour cells were removed from single, discrete metastatic foci obtained from liver, kidney, brain, spleen or intestine.

Tumour cells at the site of injection and metastases resulting from a s.c. injection of MDOW-2b tumour cells retained their Oua^R phenotype but were revertant for WGA^R (Fig. 2). Retention of the OuaR phenotype indicated that the tumour nodules originated from the injection of MDOW-2b cells and were not new tumours, induced in situ11. Similarly, all metastases resulting from s.c. MDW4 cells were revertant for the WGA^R and fucose salvage phenotypes, two characteristics of tumour cells which have previously been suggested to influence metastatic capacity 6-8,12 (Table 1). The reverted phenotype of the tumour lines derived from metastases were stable as they remained unchanged after more than 6 months in tissue culture (Fig. 1). Furthermore, injection of the cultured tumour cells established from metastatic foci resulted in rapid tumour growth (27-35 days for 50% mortality) and the same metastatic pattern of liver replacement observed with the parental tumour MDAY-D2 (Table 1).

In contrast to the metastases, not all the 'primary' s.c. growing solid tumours were complete revertants for both WGAR and fucose salvage" (Table 1). An inoculum of 102 MDW4 cells produced a solid tumour which was a 'complete revertant' (MDW4-11) while inocula of 10⁴ and 10⁵ MDW4 cells produced tumour cell populations at the site of injection which seemed to be only partially reverted for either the WGAR or fucose salvage phenotypes. The finding that injection of a low dose of MDW4 cells resulted in a solid tumour which was a complete revertant (MDW4-11), while higher doses of MDW4 produced tumours at the site of inoculation which were only partially reverted for the WGAR and fucose salvage" phenotypes (a heterogeneous population of cells), suggests, but does not prove, that the revertants did not exist in the original inoculum of MDW4 cells, but arose later in the animals and were selected as a consequence of their superior ability to survive in vivo. Hence, it seemed that the MDW4 metastases were revertant for both WGAR and fucose salvage, even in the cases where the solid tumour displayed only a partially reverted phenotype; this suggests that the cells capable of metastasizing consisted of a small subpopulation of tumour cells originating at the site of inoculation and displaying revertant phenotypes.

The results of the following experiment support this interpretation (Table 2). Intravenous injection of MDW4 cells, as already stated, even when as many as 10^5 cells are given, does not result in any tumour takes (Table 2). The same is true when nude mice are used as recipients (data not shown). However, if one mixes as few as 10 cells from a metastasis (designated MDW4-22a)—which arose in a DBA/2 mouse after s.c. injection of MDW4 cells—with 10^5 MDW4 cells, and injects the mixture i.v., 75% (n=4) of the animals rapidly develop metastases and die within 4 weeks. In view of these results and the fact that the s.c. injection of as few as 100 MDW4 cells leads to WGA-sensitive metastases (Table 1), it is difficult to argue that pre-existing cells revertant for the WGA²² phenotype in the MDW4 cell line were entirely responsible for the reported findings.

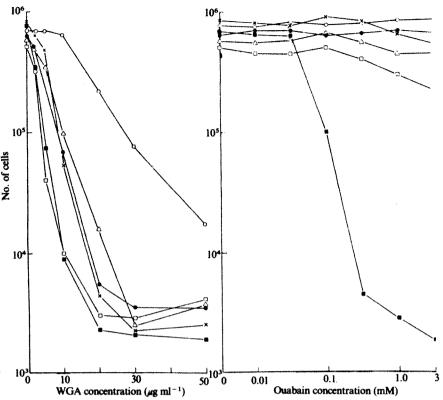

Fig. 2 WGA and ouabain sensitivity of MDAY-D2, MDOW-2b and of cell lines established from spontaneous metastases removed from the liver of an MDOW-2b-bearing mouse. DBA/2 mice were given a s.c. injection of 10⁵ MDOW-2b cells followed 60 days later by removal of tumour tissue from the site of injection (MDOW-11) and three clearly discrete metastatic nodules found in the liver (MDOW-21a, MDOW-21b, MDOW-21c). Tumour tissue removed from the mouse was minced, trypsin treated and the resulting cell suspension placed in tissue culture for at least 3 weeks to allow tumour cells to outgrow host-derived cells. The established tissue culture lines were then tested for the ability to grow in the presence of either WGA (left panel) or ouabain (right panel) as described in Fig. 1 legend; ■, MDAY-D2; ○, MDOW-2b; ×, MDOW-11; △, MDOW-21a; □, MDOW-21b; ●, MDOW-21c.

Several mechanisms can be envisaged for the generation of the revertant and more malignant phenotypes—classical genetic mechanisms of back mutation, acquisition or loss of genetic material by the tumour cells, stable regulatory changes in gene expression or somatic cell hybridization in vivo between a tumour cell and a host cell. The last possibility has been demonstrated previously¹³ but seemed unlikely in the present situation because Oua^R is a co-dominant marker⁹, such that a somatic

hybrid between Oua^R and a wild-type cell results in a partial loss of Oua^R in the resultant hybrid⁹, an event not observed for the metastases of MDOW-2b. We are now carrying out experiments to examine this possibility in more detail, and the other potential mechanisms involved in the generation of the revertant phenotypes in vivo.

The results demonstrate a need to examine the progeny, especially metastases, arising from an injection of selected

Table 1 WGAR and fucose salvage" phenotypes of subcutaneous and metastatic tumour nodules

DBA/2 mice were given a s.c. injection of the WGA^R, fucose salvage⁻ tumour cells MDW4. Seven to ten weeks after the injection of 10², 10⁴ or 10⁵ MDW4 cells, tumour tissue at the site of injection (1°) and three or four secondary metastatic nodules (2°) were removed, minced with scissors, trypsin treated to make a cell suspension and established as tissue culture lines. The cell lines derived from metastases (2°), which are listed below each primary (1°), were removed from liver, lung, spleen, brain, kidney or intestine of the same mouse. The concentration of WGA necessary to cause a 90% inhibition of tumour cell growth in tissue culture was determined as described in Fig. 1 legend.

* Tumour cells, 10^5 in $200 \,\mu$ l of culture medium, were pulse-labelled with $1 \,\mu$ Ci of L- $[6-^3H]$ fucose (27 Ci mmol $^{-1}$) and with $1 \,\mu$ Ci of L- $[4, 5-^3H]$ leucine (60 Ci mmol $^{-1}$) in parallel for 16 h at 37 °C. Acid-precipitable material was washed three times in 10% trichloroacetic acid followed by solubilization and determination of radioactivity. The ratio of fucose to leucine was determined for each cell line and the numbers in parentheses are 3H -fucose to 3H -leucine ratios expressed as a percentage of the 3H -fucose to 3H -leucine ratio for MDAY-D2. The results are the mean of three determinations performed in duplicate $\pm s.d.$

† Twelve DBA/2 mice were given s.c. injections of 10⁵ MDW4 or MDAY-D2 cells and the number of days required for 50% of the animals to succumb to the tumours was recorded. For each of the 1° and 2° tumour cell lines, four DBA/2 mice were used for the 50% mortality determinations. The tumour lines were maintained in tissue culture for at least a month before assessing their malignancy.

‡ Tumour infiltration of the liver was examined at death and described as confluent with tumour (C) or infiltrated with a limited number of nodules (N); the range is indicated in parentheses.

Table 2 Tumour takes in DBA/2 mice injected intravenously with MDW4 and cells from MDW4 metastases

Tumour cells injected	Tumour takes per no. of mice injected
MDW4 (10 ⁵)	0/8
$MDW4 (10^5) + MDW4-22a (10)$	3/4
$MDW4 (10^5) + MDW4-22a (10^2)$	4/4
MDW4-22a (10 ²)	4/4

DBA/2 mice were given a single i.v. injection of MDW4, MDW4-22a or a mixture of the two cell lines, and tumour growth was determined at death by autopsy. Animals with tumour died 25-35 days after tumour injection. Those that survived were found to be tumour free 4-5 months after inoculation. MDW4-22a refers to a cell line established from a liver metastasis which had been removed from an animal previously injected s.c. with MDW4 cells. The numbers in parentheses refer to the number of cells injected i.v.

tumour variants to determine whether or not they are phenotypically the same as the cells injected, especially when the selecting agent seems to influence the malignant potential of the variant (WGA). Tumour variants selected in vitro which display a decreased malignant potential are apparently subject to the forces which generate tumour heterogeneity in vivo. Consequently, revertant and more malignant phenotypes may

arise relatively quickly when the cells are injected into animals. Our work extends the results of Tao and Burger⁶, who have shown that WGAR variant tumour cells are often poorly metastatic. We have demonstrated that the WGAR variants may be non-metastatic and that the WGAR tumour cells must undergo phenotypic alterations, including a reversion of WGAR, before metastasis can occur.

We thank Drs Louis Siminovitch and Victor Ling for helpful discussions and Mrs B. Fluhrer and Mrs Janie Barr for secretarial assistance. This work was supported by the NCI of Canada, of which R.S.K. is a Research Associate.

A single dominant gene determines susceptibility to a leukaemogenic recombinant retrovirus

Robert S. Schwartz & Raman H. Khiroya

Department of Medicine, Tufts University School of Medicine, Boston, Massachusetts 02111, USA

The production of recombinant retroviruses is an important episode in the natural history of thymic leukaemia in AKR and HRS/J (hr/hr) mice^{1,2}. These viruses apparently originate from ecotropic and xenotropic precursors in the late preleukaemic stage of the disease. Analyses of their structural proteins^{3,4} and genomic oligonucleotides^{3,5} indicate that they arise by recombination of env genes of the precursor viruses. This event leads to a viral envelope glycoprotein (gp70) with some peptides that have features of the gp70 glycoproteins of ecotropic and xenotropic viruses, and others that are unique for each recombinant virus^{3,4,6}. The former property explains the broad host range of recombinant viruses, and hence their designation as dual tropic1 or polytropic² viruses. It has been postulated that the unique aspect of each recombinant's gp70 determines the phenotypes of leukaemic cells7. Polytropic viruses may be highly thymotropic. Their systemic administration results in an infection that confines itself virtually to the thymus^{3,8}. Moreover, these viruses are leukaemogenic whereas their precursors are not, or only weakly so^{3,8,9}. The leukaemogenicity of polytropic viruses is, however, restricted to certain inbred strains of mice^{3,8}. The HRS/J isolate PTV-1 is leukaemogenic in HRS/J and CBA/J mice, but not in SWR/J or NIH/Swiss mice³. The experiments described here demonstrate that a single dominant gene permits infection of thymocytes by a leukaemogenic polytropic virus. CBA/J mice, which develop thymic leukaemia after infection by this virus, posesses this gene, whereas leukaemia-resistant NFS mice lack it.

Figure 1 shows the results when newborn mice were inoculated with 10³-10⁴ focus-forming units (FFU) of a cloned polytropic virus, PTV-1. This thymotropic virus is leukaemogenic in CBA/J, but not in NIH/Swiss mice or their inbred counterpart, NFS (ref. 3 and unpublished observations). Its gp70 and genomic RNA are typical of a recombinant virus³. The mice were killed 4-6 weeks after inoculation and the levels of polytropic virus in their thymuses were measured by an infectious centre assay10. Polytropic virus is undetectable in uninoculated animals of the strains used in these experiments³.

CBA/J mice were readily infected by PTV-1, whereas NFS mice had either low or undetectable levels of virus. F₁ mice behaved like CBA/J mice. Susceptibility to PTV-1 is therefore a dominant trait. The upper limit of resistance (100 FFU per 10⁷ thymocytes) was defined by the mean + 2 s.d. of the results in NFS mice and the lower limit that defined susceptibility (440 FFU per 10⁷ thymocytes) was taken as the mean – 2 s.d. of the results in CBA/J mice. The 66 backcrosses to the NFS parent segregated, by these standards, into susceptible and resistant mice in a ratio of 38:28. This ratio is not significantly different from 33:33 ($\chi^2 = 0.88$, P > 0.1). The corresponding ratio in 61 F₂ mice was 44:17, which is not significantly different from 45:15 (3:1) ($\chi^2 = 0.14$, P > 0.1). Exclusion of the eight F_2 mice with intermediate values (between 100 and 440 FFU per 10⁷ thymocytes) does not change the significance of the result $(\chi^2 = 0.53, P > 0.1)$. All backcrosses to the CBA/J parent were susceptible. These results are consistent with the conclusion that a single dominant gene confers susceptibility to infection by PTV-1. We shall refer to this gene as PTV^s .

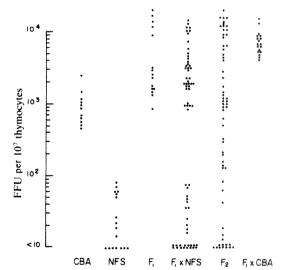

Fig. 1 Results of infection with PTV-1. Mice were injected intraperitoneally with 10^3-10^4 FFU of PTV-1 within 24 h of birth. The animals were killed 4-6 weeks later and cell suspensions prepared from their thymuses. These cells were tested by an infectious centre assay³ on mink lung cells (CCL64). X-C negative viruses capable of infecting both mink and mouse (NIH 3T3) cells were detected in all CBA/J mice injected with PTV-1. Neither mink-tropic nor mouse-tropic viruses can be detected in agematched uninjected CBA/J or NFS mice.

Table 1 Results of infection with ETV-1 (cloned ecotropic retro-

	CBA	NFS
ETV-1	3.3 ± 0.7	3.5 ± 1.2
PTV-1	3.1 ± 0.4	0.9 ± 0.5

Mice were injected intraperitoneally with 10³-10⁴ FFU of ETV-1 within 24 h of birth. The animals were killed 4-6 weeks later and thymocytes were tested in an infectious centre X-C assay¹. Values for ETV-1 are expressed as \log_{10} X-C plaques/ 10^7 thymocytes \pm s.e. Data for PTV-1 are taken from Fig. 1.

The mechanism whereby PTV's confers susceptibility to PTV-1 is unknown. Its action is specific for the polytropic virus, because NFS mice are as susceptible as CBA/J mice to infection by a cloned ecotropic virus (Table 1). The effect of PTV^s does not seem to be immunological because CBA/J and NIH/Swiss

mice produced comparable levels of antiviral antibodies after neonatal infection with either PTV-1 or an ecotropic virus (unpublished observation). We favour the view that this gene specifies a receptor on thymocyte surface membranes for the constant region⁶ of recombinant gp70 because that glycoprotein is a major determinant of viral host range¹¹. The specificity of PTVs for the recombinant virus (Fig. 2) supports this interpretation, as the only known difference between viruses of this type and ecotropic viruses is in the gp70 (refs 3,4,6). We cannot exclude an effect that would be analogous to that of Fv-1, which acts after penetration of the virus¹². This possibility seems unlikely, however, because PTV-1 readily infects NIH 3T3 cells in vitro³. Finally, the present results support the view ^{3,8} that the highly selective thymotropism of certain polytropic viruses is an important factor in their leukaemogenicity.

Sequence and specificity of two antibacterial proteins involved in insect immunity

H. Steiner*, D. Hultmark*, Å. Engström†, H. Bennich† & H. G. Boman*

*Department of Microbiology, University of Stockholm, S-106 91 Stockholm, Sweden [†]The Biomedical Centre, University of Uppsala, S-751 23 Uppsala, Sweden

Immune responses have been described for many different insect species1. However, it is generally acknowledged that insects lack lymphocytes and immunoglobulins and their immune systems must therefore differ from those of vertebrates. An effective humoral immune response has been found in pupae of the cecropia moth, Hyalophora cecropia¹. The expression of this multicomponent system requires de novo synthesis of RNA and proteins² and its broad antibacterial activity is due to at least three independent mechanisms³, the most well known of which is the insect lysozyme⁴⁻⁷. However, this enzyme is bactericidal for only a limited number of Gram-positive bacteria. We recently purified and characterized P9A and P9B, which are two small, basic proteins with potent antibacteral activity against Escherichia coli and several other Gram-negative bacteria⁷. We believe that P9A and P9B play an important part in the humoral immune responses described previously and that the P9 proteins represent a new class of antibacterial agents for which we propose the name cecropins. We describe here the primary structures of cecropins A and B. We also show that cecropin A is specific for bacteria in contrast to melittin, the main lytic component in bee venom9 which lyses both bacteria and eukaryotic cells.

A two-step chromatographic purification of cecropins A and B has been recently described⁷. This purification was improved for sequence work by first using gel filtration on Sephadex G100.

The tentative sequences of both cecropins are given in Fig. 1. Residues 1-33 were obtained by automated Edman sequence analysis and the order of the C-terminal residues 34-37 was deduced from carboxypeptidase Y degradations. This part of the sequence is tentative until confirmed by an independent method. The C-terminal Lys and Ser residues could only be detected after acid hydrolysis of the carboxypeptidase digest; therefore we conclude that the C-terminals are blocked.

The cecropins have very similar overall structures. The Nterminal sequences (residues 1-10) are strongly basic and the central regions (residues 22-30) strongly hydrophobic. The amino acid compositions obtained from the sequences and from automated analyses are compared in Table 1. The agreement between the two sets of data support the structures shown in Fig. 1. Further evidence for the sequences was obtained by partial cleavage of cecropin A at residue 17 using acid hydrosis 10 and isolation of the C-terminal fragment by high-voltage electrophoresis. The amino acid composition of this peptide was in agreement with the structure given in Fig. 1. Cecropin B was cleaved by cyanogen bromide at the single methionine in position 11 and the resulting fragments analysed. This analysis confirmed the order and identity of residues 1-33 but despite several different approaches, we have failed to obtain Edman sequencing data for residues 34-37.

Table 1 Amino acid compositions of cecropins A and B

Amino	Amino Cecropin A		Cecro	pin B
acid	Analysis	Sequence	Analysis	Sequence
Asp	2.01*	1	2.15*	0
Asn		1		2
Thr	1.07	1	0.33	0
Ser	0.17	0	0.53	1
Glu	3.89*	1	1.95*	2
Gln		3		0
Pro	0.95	1	1.04	1
Gly	4.05	4	4.07	4
Ala	4.88	5	4.84	5
Cys	0	0	0	0
Val	3.31	4	2.47	3
Met	0	0	0.80	1
Ile	3.65	5	3.48	5
Leu	1.09	1	1.95	2
Tyr	0	0	0.10	0
Phe	0.98	1	0.87	1
Lys	6.42	7	6.75	7
His	0.06	0	0.29	0
Arg	0.94	1	1.98	2
Trp		1		1
Total residues		37		37

Amino acid composition of the acid hydrolysate (6 M HCl, 100 °C, 24 h) of cecropin A was analysed at the Institute of Biochemistry, Uppsala, Sweden. The results are expressed as mol amino acid per mol protein. These values were calculated with a program that minimizes the deviations from integral numbers.

* Including the corresponding amide.

Fig. 1 The tentative amino acid sequence for cecropins A and B. Replacements of amino acids within the first 33 residues are boxed by solid lines. The C-terminal part boxed by a broken line is tentative. R and R' are unidentified blocking groups. The purified proteins used in sequence determination were obtained by collecting immune haemolymph 7 days after vaccination with live Enterobacter cloacae as previously described. The haemolymph was applied to a Sephadex G-100 column equilibrated with 0.15 M ammonium acetate buffer, pH 5, containing phenylthiourea. The cecropins eluted together with the lysozyme. This material was pooled and further purified by ion-exchange chromatography.

Both forms of cecropin contain one residue each of Trp and Phe. On this basis the theoretical absorbance $(A_{280}, 1 \text{ mg ml}^{-1})$ was calculated to be 1.39 and 1.38 for cecropins A and B, respectively, which agrees well with the respective values of 1.36 and 1.31 determined experimentally, based on the protein concentration obtained from amino acid analysis. This means that an earlier value for cecropin A based on Lowry determination must now be disregarded.

The molecular weights (MWs) calculated from the sequence data (omitting the blocking groups) are 4,005 and 4,036 for cecropins A and B, respectively. Equilibrium centrifugation of cecropin A in 0.19 M ammonium formate, pH 6.5, gave a MW of 4,200±300, which indicates a monomeric form. Furthermore, dimethylsuberimidate did not produce any cross-linking between cecropin molecules in conditions which showed melittin to be a tetramer. In contrast, gel filtration of cecropin A on a calibrated column of Sephacryl S-200 gave a MW of ~14,000. On Sephadex G-100, cecropins A and B eluted together with the lysozyme for which the MW was found to be 15,000 (ref. 7). Thus we cannot determine whether cecropin A is always a monomer.

The following points emerge from the structure of the cecropins. First, the sequences obtained for cecropins A and B show a strong homology; they share 25 amino acid residues and differ in only 12. This suggests that both originate from a gene duplication which may stretch only to residue 32. Assuming that the genetic code is universal, 7 out of 8 amino acid replacements in the first 32 residues can be explained by single shifts in the first base, while the remaining one, a Gln-Arg shift requires a single shift in the second base. More complicated genetic events are needed to explain the amino acid differences in the C-terminal part.

Second, the cecropin sequences have been compared with various other known protein sequences and the greatest
